INTRODUCING THE RAPID ROUTE TO CUSTOM PEPTIDES

FOR ANTIPEPTIDE ANTIBODY PRODUCTION-

CRB | **CUSTOM
EXPRESS** |

CRB have developed great experience in the **Selection** and **Synthesis** of **PEPTIDES** for use in the generation of **Antipeptide Antibodies** to oncogenes, growth factors, viral and bacterial coat proteins etc., together with expertise in Peptide Conjugation Techniques, Immunisation Protocols and Assay Procedures.

As an addition to our existing services for molecular biology, CRB now offers an **EXPRESS SERVICE** (2-3 weeks) for the custom synthesis of such peptides. These **Guaranteed** products (>80%) are supplied at **Low Cost** with **Comprehensive Analytical Data** (hplc, amino-acid analysis and fast atom bombardment mass spectrometric analysis).

Peptide-carrier protein **Conjugates** may also be prepared rapidly and economically by a variety of methods directed to the production of more carefully defined conjugates.

Other CRB services include Hydrophilicity Analysis, Epitope Mapping and Determination of Antibody Specificities, synthesis of internally Radiolabelled Peptides etc. CRB is also developing a New Immunisation Protocol for the high yield production of monoclonal antibodies.

For further details, or for any information concerning the use of, or application of, synthetic peptides please contact: Dr Paul W Sheppard, Contract Research Director.

NATURE VOL. 318 7 NOVEMBER 1985

COVER

Shrinkage cracks in montmorillonite-water gel deposited on a glass slide. The filaments, which consist of oriented aggregates of small platelets, will re-expand on contact with water to fill the spaces. But this ability is destroyed by reaction with steam, with possible consequences for the efficiency of clay barriers proposed for nuclear waste repositories. See p.50.

"Demand high resolution in preparative ion exchange chromatography"

New! Q and S Sepharose® Fast Flow ion exchangers from Pharmacia.

You as a chromatographer should be aware of the new strong ion exchange media from Pharmacia. These new gels offer you excellent resolution in preparative ion exchange chromatography, and no media are easier to handle.

By selecting strong ion exchange groups, Pharmacia has created two gels with the ability to work at the pH most appropriate to the stability of your sample and the separation required: Q Sepharose Fast Flow for anion exchange and S Sepharose Fast Flow for cation exchange.

Simplicity and resolution in ion exchange chromatography!

Just look at the resolution you can expect in a typical preparative run! In cases where resolution is not critical, the outstanding flow properties of Q and S Sepharose Fast Flow give you faster separation. Their

very high capacity means that you can load plenty of material in every run, saving time and money. Under harsh running conditions and during column regeneration, the gels display outstanding chemical and physical stability. And if you are moving up to large scale separation, you won't find a better starting point than Q and S Sepharose Fast Flow.

Don't delay! Order your gels now. Further information is available free on request.

 **Pharmacia**

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from *Nature* should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.

ProtoBlot™ Immunoscreening System

The ProtoBlot™ system allows immunological detection of cloned DNA expressed in Proclone™ GT λ gt11 or other expression vectors.

Promega Biotec's ProtoBlot™ system offers you:

Ten times the sensitivity of peroxidase based systems

Highest signal-to-noise ratio available

Non-isotopic detection with better performance than ^{125}I Protein A

Detects **either** rabbit or mouse primary antibodies

Simple, easy to use protocol

Positive control anti- β -galactosidase monoclonal antibody can also be used for Western blotting or immunoprecipitation of fusion proteins

All components also available separately

λ gt11 has become increasingly popular as a vector for the construction of cDNA libraries, specifically because of its ability to express high levels of desired products as proteins. Cloning into the lac Z gene can result in the expression of foreign DNA as part of a β -galactosidase fusion protein which can be detected with antibodies. The ProtoBlot immunoscreening system allows the use of your rabbit or mouse primary antibodies as probes to detect λ gt11 recombinants containing DNA sequences of interest.

The system consists of the highest quality affinity purified second antibody alkaline phosphatase conjugates and the necessary color development substrates. A positive control is included consisting of a recombinant λ gt11 ovalbumin clone and mouse anti- β -galactosidase monoclonal antibody. Also included is an *E. coli* lysate for background

reduction in cases where primary antisera contain crossreacting nonspecific antibodies. We provide an easy, detailed protocol for obtaining results in less than three hours.

The ProtoBlot immunoscreening system employs alkaline phosphatase conjugated second antibodies for greatest sensitivity and maximum signal-to-noise ratios. The figure below demonstrates the increased sensitivity of alkaline phosphatase conjugates relative to horseradish peroxidase (HRP) conjugates. The left hand panel shows the results of an actual screening experiment, while the right hand panel quantitates the limits of sensitivity of both methods. The data clearly show that the ProtoBlot system is at least 10-fold more sensitive than HRP based systems. This could mean the difference in having to rescreen or reconstruct your cDNA library, or in having to obtain more primary antibody.

A. Plaque lift comparison. Approximately 20 recombinant λ gt11 phage containing an ovalbumin cDNA were plated with 10^4 λ gt10 phage on a Y1090 host. After a 3.5 hour incubation at 42°C the plates were overlaid with IPTG soaked nitrocellulose filters and incubated for another 3.5 hours at 37°C. The filters were processed according to recommended protocols with either alkaline phosphatase conjugated second antibodies (ProtoBlot system, upper left) or horseradish peroxidase conjugates (lower right). The primary antibody in both cases was a rabbit anti- β -galactosidase IgG fraction, which detects the ovalbumin/ β -galactosidase fusion protein expressed by the λ gt11 recombinants. Low backgrounds are indicated by the absence of visible λ gt10 plaques.

B. Dot blot comparison. The indicated amounts of purified β -galactosidase were spotted in one microliter volumes on nitrocellulose. The filters were processed under the same conditions as the plaque lifts. Development times in both experiments were 6 minutes for the ProtoBlot system (left lane) and 30 minutes for the HRP system (right lane).

A computer-generated model of a novel molecule formed by laser irradiation of graphite. The 60-carbon molecule is remarkably stable, with a structure akin to a truncated icosahedron — a polygon with 60 vertices and 32 faces, 12 of which are pentagons and 12 hexagons — a geometrical pattern commonly encountered in the form of a football (soccer, that is). See page 162.

Something Special

Imagine the world's simplest operating ultracentrifuge. Add the most reliable drive ever designed—the Ultra-Smooth vacuum-encased induction system. Include automatic "Soft-Start," built-in diagnostics and the ability to run every Beckman high performance rotor. Top it off with a most attractive purchase price. And you have the new Model L7-55—the one you have been asking for.

With speeds to 55,000 rpm, forces to 408,000 *g*, integrated circuit logic and remarkably

simple controls, the L7 is ideal for everyday applications. It's the perfect addition to the Beckman family of induction drive ultracentrifuges, joining the premier L8M models—the ultimate in centrifugal research tools—and the Benchtop TL-100 for rapid microvolume separations.

Use the L7 for the routine jobs. Save your L8M for investigations where microprocessor control and memory are an advantage, where delicate gradients call for acceleration/deceleration versatility, where computer

interfacing is needed for remote control or record keeping. When you want to cut run times for these jobs by more than half, use the TL-100.

The workaday Model L7-55: it's something special—especially for you!

To get better acquainted, ask for Brochure SB-667. Beckman Instruments, Inc., Spinco Division, 1050 Page Mill Road, Palo Alto, CA 94304.

oncor[®] Human *myc* Antibody

Oncor announces the successful development of affinity purified anti-human *myc*. This polyclonal sheep antibody has been qualified for the detection of human *myc* protein by immunofluorescence and western blot procedures.

Each vial of freeze dried anti-human *myc* contains enough affinity purified antibody to carry out 25 western blot procedures. When diluted according to instructions, the antibody concentration is 200 μ g/ml.

Performance tested antibodies which complement **oncor probes[™]** for oncogene research include:

CAT #	PRODUCT	DESCRIPTION	PRICE*	
			1-2	3+

nature

NATURE VOL. 318 21 NOVEMBER 1985

COVER

A 'religious' style of map-making flourished in eighteenth-century China, alongside the more scientific tradition. China is allotted the central place of honour, surrounded by fabulous seas and mythical countries, plus a few real countries including Korea and Japan. Science in twentieth-century China is the subject of this week's supplement, starting on page 205. (Map published circa 1800 in Korea; by permission of the British Library.)

SCIENCE IN
CHINA

How is China's science recovering from the Cultural Revolution? Is the Chinese government right to expect that science and technology will quadruple the country's wealth by the end of the century? And how is research responding to the challenge? Alun Anderson and John Maddox deal with some of these questions in Nature's special issue on 21 November, 1985.

- Australia's oldest mammal
- New Zealand glaciations
- Oriented crystal growth
- High energy emissions from Hercules X-1

- GUIDE TO AUTHORS -

Authors should be aware of the diversity of *Nature's* readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

BIO/TECHNOLOGY INVITES YOU TO ATTEND ITS
PREMIER CONFERENCE

BIO/TECHNOLOGY

LOOKS TO THE NEXT DECADE

January 20-22, 1986—New Orleans

BIO/TECHNOLOGY Looks to the Next Decade will go beyond most scientific symposia. First and foremost, the conference will bring together some of the world's leading authorities in molecular biology and process technology in a setting modeled after the very best of the invitation-only conferences. Everything is designed to provide a maximum exchange of ideas and information.

A look at the roster of keynote speakers, all leading researchers in their fields, demonstrates at a glance that only the highest level of scientific information will be presented.

To insure the greatest possible interaction and exchange, each afternoon will be devoted to roundtable discussions chaired by the keynote speakers, and featuring panelists of the highest calibre. There will be opportunity for all attendees to make brief presentations during these sessions, and participants are urged to bring their own slides.

If you want to get a jump on the ideas and techniques that will guide biotechnology through the '80s and '90s—this conference is for you.

Participation will be limited to provide maximum opportunity for fruitful exchange. So don't delay. Register now to guarantee your place.

CONFERENCE PROGRAM & SPEAKERS

JANUARY 20—MORNING

THE MOLECULAR BIOLOGY OF PLANTS AND ANIMALS: A VIEW FROM THE FRONTIER

SPEAKERS:

David Goeddel
Director, Molecular Biology, Genentech

Richard Flavell
President, Biogen Research Corp.

Norman Borlaug
CIMMYT, Mexico City and Professor, Dept. of Soil and Crop Science, Texas A&M

Robert Fraley
Manager of Plant Molecular Biology, Monsanto

David Evans
Vice President for Research, DNA Plant Technology, Inc.

Charles Arntzen
Associate Director of Central Research and Development, E.I. Du Pont de Nemours and Co.

JANUARY 20—AFTERNOON

SEMINAR IN MOLECULAR BIOLOGY PANELISTS

COVER

The opalized remains of Australia's first-known Mesozoic mammal, an Early Cretaceous monotreme from Lightning Ridge, New South Wales. Its structure supports the view that monotremes are closely related in terms of evolution to the other two groups of living mammals — the marsupials and placentals. See page 363 and News and Views p.313. (Photo: John Field.)

At your service! a unique combination.

Fulfill all your requirements from the combined features of pUC18/19, M13 and T7 promoted transcription

- **Sequencing** the f1 origin and the M13 helper phage will readily convert your double-stranded plasmid into ssDNA.
- **Mutagenesis** use your ss-template for site directed mutagenesis, no subclonings needed.
- **Hybridization** prepare your probes by reversed priming or transcription from the T7 promoter.
- **Transcription** produce micrograms of full-length RNA using T7 promoted transcription.

A complete "All-in-one" system.

- Interstellar ions in solar wind
- Ionospheric response to interplanetary magnetism
- Etna's larva dated
- Aphid sex ratios
- Tumour promoters and *ras*
- Penicillin resistance
- Astrology put to test

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature's* readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

A brighter idea from Olympus

*LWD CD Plan 20X,

phase contrast illumination

**Phagocytosis of fluorescent particles by peritoneal macrophages as revealed under a fluorescence microscope.
*Photographs were supplied through the courtesy of Hiroshi Maeda Ph.D., M.D., and Tatsuya Oda Ph.D.,
Department of Microbiology, Kumamoto University Medical School, Kumamoto, Japan.*

More brilliant, crisper images improve fluorescence observation and photomicrography.

Responding to the research demands of the medical, biological, bio-technological, and industrial fields, Olympus has developed new optics to ensure a brighter, more distinct fluorescent image. The result is an array of new reflected-light fluorescence attachments for use with the advanced computerized NEW VANOX research photomicroscopes, the high quality BH-2 system microscopes, and the IMT-2 inverted microscope.

Switchover between different excitation wavelengths can be accomplished with a minimum of effort. And for each excitation wavelength, a sharper, brighter fluorescent image is assured thanks to Olympus' new optical technology.

Best of all, for the most sophisticated research needs, simultaneous observation of reflected-light fluorescence as well as transmitted light phase contrast images of non-fluorescent areas is possible. Olympus—providing a brighter way to improve fluorescence microscopy.

COVER

The developing pattern of expression of the *engrailed* gene in an early *Drosophila* embryo. At later stages the pattern of expression of *engrailed* corresponds to that of morphological segmentation, but the cover photograph shows this is preceded by a stage with a two-segment periodicity. As discussed on page 433 of this issue, this could reflect a fundamental aspect of the pattern-forming process of embryonic segmentation.

THE LANGMUIR-BLODGETT INSTRUMENT

If advanced molecular electronics is your field of interest, this is the Langmuir-Blodgett instrument for you. KSV offers state of the art thin film technology of tomorrow... today. The new KSV 2200 LB monolayer laboratory achieves the performance and reliability demanded by the fabrication of the most sophisticated LB-films.

The Automatic Film Collector system was developed to allow unsupervised deposition of ordered layers of LB-films, while consistent quality is guaranteed by the microprocessor-controlled Dynamic Film Control system.

The requisite ultra-clean atmosphere is created by the rugged laminar flow enclosure.

To make things even better, you have direct access to the KSV 2200 LB system from your personal computer through a standard RS-232C serial interface. Convenient and rapid data acquisition and processing with KSV-software means flexibility and fast analysis of results – with the swiftness and accuracy you have only dreamed about. You can concentrate on the information, not the instrumentation.

Discover the state of the art thin film technology with KSV 2200 LB – the leader in Langmuir-Blodgett films.

If you're involved in microbiological research, you've been waiting for a breakthrough like Bioscreen.

Bioscreen is a new fully-automated analyzer system that kinetically measures the growth of micro-organisms. Ideal for applications involving bacterial growth detection, inhibition, enhancement and bioassays, Bioscreen:

- Eliminates many labour-intensive procedures.
- Works as a complete system with integrated dispensing, incubating, measuring and data handling.
- Utilizes vertical photometry to ensure more accurate results.
- Provides far more detailed information than previously possible in the form of individual growth curves.
- Has a throughput of up to 200 tests simultaneously.

Bioscreen has been developed by Labsystems – a leading manufacturer of photometers, analyzing systems, diagnostics and liquid dispensers. Contact either your nearest Labsystems subsidiary or us direct for further information and a demonstration.

Do you get this kind of accuracy from your present Pipette?

Each and every Labsystems' Finnpiquette is manufactured to the kind of levels of accuracy and precision shown above. What's more, it's also been calibrated gravimetrically using a computer-controlled microbalance. So you can simply take it out of the package and start work right away.

And then you'll discover the famed Finnpiquette ergonomic design – in other words, your pipette almost becomes an extension of your hand. An extension that causes neither stress nor strain even during repeated dispensing. Furthermore, because your Finnpiquette is made from the highest quality materials, it stands up to the rigours of laboratory life better than most.

Whatever your requirements, you'll find a Finnpiquette to meet them – from the world's first continuously adjustable micropipette, to our latest digital and positive displacement models. Single or multichannel, too. And we also supply a complete range of high quality disposables.

But don't just take our word for it. Get in touch with your nearest Labsystems Finnpiquette dealer or us direct and try out a Finnpiquette for yourself.

- Archaeobacterial intron
- Vaccinia virus uses epidermal growth factor receptor
- Tumour necrosis factors and insulin
- New Duchenne muscular dystrophy marker

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc., should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc., should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

At last!

An easy to use gene machine at an affordable price.

Now any laboratory working with oligonucleotides can perform automated DNA synthesis simply, reliably and affordably—whatever the volume demand—with the new Pharmacia Gene Assembler™. This high-quality system combines state-of-the-art technology and chemistry with simplicity of design and operation.

Integral

The Gene Assembler is a complete system. The bench-top, fully-automated machine is a compact, self-contained unit that includes everything you need to synthesize active DNA: modular-designed hardware, intelligent software, a precision delivery system, Pharmacia's own reagents, and a comprehensive handbook.

The system also includes automatic colorimetric monitoring and a built-in printer/plotter that gives you a permanent record of each synthesis in both peaks and print.

Simple

The Gene Assembler was designed for maximum ease of operation. You just insert a ready-to-use MonoBeads™ matrix cassette into one of the column reactors, type in the desired sequence and let the machine do the rest. It's not only self-contained, it's very nearly self-sufficient!

Flexible

You don't need any peripheral hardware (an expensive "option" with some competitors). The Gene Assembler is preprogrammed for everything from standard syntheses to so-

phisticated mixed bases. And it's versatile enough to allow user-determined reprogramming—for modified nucleotides, for example. If you want even greater capacity, though, it can easily interface with a variety of other microcomputers.

Affordable

Pharmacia's expertise in biotechnology enabled us to optimize components to form a dedicated system. Therefore, designing and manufacturing the Gene Assembler cost substantially less than competitive machines. That saving is passed along to you.

In addition, the system uses the latest β -cyanoethyl phosphoramidite chemistry and has two column reactors for sequential synthesis. All in all, this high-quality, high-performance system is the most efficient and cost-effective DNA synthesizer you can buy.

Reliable

As with all Pharmacia equipment, the Gene Assembler consists of high-quality components, each designed to give you years of dependable service. Of course, it's also backed by Pharmacia's established, worldwide service network and warranty.

Available

Pharmacia has prepared a comprehensive, illustrated brochure that will tell you everything you want to know about the Gene Assembler. Contact your local Pharmacia representative directly and ask him to send it to you today. You can also write or call:

Your Link With The Future

WHAT IMPACT ARE NEW BIOTECHNOLOGY TECHNIQUES HAVING ON MEDICINE WORLDWIDE TODAY?

Come to Nature's 7th International Conference in London on Molecular Biology in Medicine 1986 for all the up to date facts — and a look into the near future.

NEW TECHNOLOGY
in
BIOTECHNOLOGY

MOLECULAR BIOLOGY IN MEDICINE
a survey of its achievements and its potential
JUNE 18-20 1986 — LONDON

It is clear that the modern techniques of biotechnology are set to have a major impact on medicine. Over the next few years many new opportunities will emerge. This important conference will provide a wide-ranging survey of the most recent research in the fast changing field of molecular biology in medicine, and a look into the future. If you want an opportunity to see and hear for yourself what leading exponents have achieved in recent years — and to learn what new opportunities are on the horizon, come and join us. You'll find a booking form below.

JUST SOME OF THE NEW OPPORTUNITIES YOU CAN FIND OUT ABOUT FIRST HAND AT NATURE'S 7TH INTERNATIONAL CONFERENCE.

DIAGNOSTICS

- Monoclonal antibodies to speed up and simplify laborious tests.
- engineered antibodies to provide further sophistication.
- gene probes to allow the detection of mutations that are linked to cancer.

THERAPEUTICS

- the discovery of new families of proteins and peptides with potential clinical value.

the means to engineer proteins so as to improve their therapeutic value.

the use of monoclonal antibodies to target drugs to tissues.

PREVENTION

the first potential vaccines against several infectious diseases, such as malaria.

the refinement of existing vaccines.

the detection of genetic defects with sufficient confidence and speed to prevent or limit their damage.

AMONG THE LIST OF TOP CALIBRE INTERNATIONAL SPEAKERS WILL BE

G. Schild, National Institute for Biological Standards and Control, UK
A. Capron, Institut Pasteur, Lille, France
S. Gillis, Immunex, US
M. Neuberger, LMB, Cambridge, UK
L. Montagnier, Institut Pasteur, France
K. Sikora, Ludwig Institute, Cambridge, UK
R. Gerety, Merck Sharp & Dohme, US
T. Waldmann, NIH, US
R. Baldwin, Nottingham, UK
E. Tuddenham, Royal Free Hospital, UK
D. Weatherall, Oxford, UK
W.F. Anderson, NIH, US

OUR THREE DAY PROGRAMME ENABLES YOU TO ASSESS IMPORTANT NEW BIOTECHNOLOGY TECHNIQUES IN MEDICINE. MEET INTERNATIONAL RESEARCH SPECIALISTS, AND DISCUSS WHAT YOU LEARN WITH NEW CONTACTS FROM AROUND THE WORLD.

JOIN US AT NATURE'S 7TH INTERNATIONAL CONFERENCE, TO BE HELD AT THE LONDON WEST HOTEL, JUNE 18-20 1986.

REGISTER NOW TO ENSURE YOUR PLACE — SPACE IS LIMITED.

The **CONFERENCE FEE** is just £189 plus VAT for the three days of the conference. This includes entrance to all sessions, mid-morning coffee, afternoon tea and reading material. Group discounts are available on application to Janine Slipman, Macmillan Conferences and Exhibitions, 4 Little Essex Street, London WC2R 3LF, UK, Telephone (01) 836 6633.

Book before January 31st and we'll send you Nature's 1986 calendar FREE!

ACCOMMODATION has been reserved in the London West Hotel for conference participants. A booking form will be sent to you as soon as we receive your registration.

TECHNICAL SEMINARS and **POSTER SESSIONS** will be held each day.

THE NEW GENERATION IN DNA SYNTHESIS REAGENTS

β -LINK™

**EXCLUSIVELY
FROM
BIOSEARCH**

**CALL TOLL-FREE:
(800) 227-2624**

β -link DNA Synthesis Reagents make it possible to synthesize very pure, short or long (greater than 170 bases) DNA fragments more easily and more economically than ever before.

Typical stepwise yields exceed 99%. Cycle time is less than 6 minutes. And the β -link synthesis method uses a single-step deprotection procedure that eliminates potential side reactions.

β -link DNA Synthesis Reagents. Packaged conveniently for all your DNA synthesis needs.

Available exclusively from Biosearch.*

NATURE'S GUIDE TO HOW BRITAIN RUNS ITS SCIENCE

Nature's practical and useful wallchart has now been thoroughly updated. It provides a complete survey of the administration of British science, showing the functions, key personnel and finance of

- Government departments
- Public and independent bodies
- Research councils

Easily carried to meetings or hung as a wall poster for permanent reference, the new Nature wallchart is an ideal source of reference.

GUIDE TO AUTHORS

Authors should be aware of the diversity of *Nature's* readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an italic heading of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington. Manuscripts should be typed (double spacing) on one side of the paper only. Four copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc., should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc., should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts, in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. Reference to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

BIO/TECHNOLOGY INVITES YOU TO ATTEND ITS
PREMIER CONFERENCE

January 20-22, 1986—New Orleans

BIO/TECHNOLOGY Looks to the Next Decade will go beyond most scientific symposia. First and foremost, the conference will bring together some of the world's leading authorities in molecular biology and process technology in a setting modeled after the very best of the invitation-only conferences. Everything is designed to provide a maximum exchange of ideas and information.

A look at the roster of keynote speakers, all leading researchers in their fields, demonstrates at a glance that only the highest level of scientific information will be presented.

To insure the greatest possible interaction and exchange, each afternoon will be devoted to roundtable discussions chaired by the keynote speakers, and featuring panelists of the highest calibre. There will be opportunity for all attendees to make brief presentations during these sessions, and participants are urged to bring their own slides.

If you want to get a jump on the ideas and techniques that will guide biotechnology through the '80s and '90s—this conference is for you.

Participation will be limited to provide maximum opportunity for fruitful exchange. So don't delay. Register now to guarantee your place.

CONFERENCE PROGRAM & SPEAKERS

JANUARY 20—MORNING

THE MOLECULAR BIOLOGY OF PLANTS AND ANIMALS: A VIEW FROM THE FRONTIER

SPEAKERS:

David Goeddel

Professor of Biophysics and Biotechnology, Tel Aviv University, Israel

Where has all the stuffing gone?

British universities seem ill-equipped to fight back against their most obdurate critic, the government whose instrument of policy on higher education they are supposed to be.

BRITISH universities have had a rotten time in the past few years. Is it possible that their painful experiences have made them incapable of resisting the continuing pressure from their critics, chiefly the British government? That is the charitable explanation of the mood of last week's conference, organized by the universities' trade association, the Committee of Vice-Chancellors and Principals, which was ostensibly intended as a forum for hammering out a reply to the government's green paper on higher education, published earlier this year (see *Nature* 315, 265; 1985). That the committee should have it in mind to reply to the government's tactless document by producing the one that should have been published, cheeky though it may be, is sound. The danger is that the result will not be a defence but a kind of apology, like that of the legendary servant girl who was in trouble for having produced a child of unknown parentage and whose defence was along the lines of "but it's only a small one".

To be fair, the universities seem to have taken account of one of the features of the British educational system that cries out for reform. Several speakers at last week's conference spoke of the need for a broader curriculum both at the secondary schools from which the universities recruit their students and even within universities themselves. It is high time, in the apparently endless brooding about the failure of the British system of higher education, that more serious attention was paid to the value of a liberal education. Indeed, the need that something should be done to make British education less narrow has been urgent at least since the rapid expansion of the early 1960s. For much of that time, British academics have been chief among those seeking to resist change. Only reluctantly, in the past few years, have they been won round to a reform of the pattern of school education that will allow a modest broadening of the education of intending students, no doubt in part because they appreciate that it cannot harm the university system if it becomes more common that students should follow four-year undergraduate courses (as they do already in Scotland). The trend is nevertheless a sign of grace.

Research

On research, the universities seem less sure of themselves. The tenor of the British government's complaint is that too much of what passes for research at British universities is academic in character, unlikely to contribute to national prosperity. This is the spirit in which the budget cuts have been put forward as beneficial incentives to be more practical. Driving academics looking for funds into the arms of industry is bound to make their work more directly relevant to national prosperity, the argument goes. The reply on behalf of the universities last week was curiously muted. Universities have a snobbish disdain for industry (as the green paper complains)? "That cannot be true now; just look at the difficulty we have in persuading graduates to stay on for research!" Universities have been slow to assist with the transfer of technology to industry (another complaint)? "Ah well, things are changing; some universities are making substantial sums of money out of industrial liaisons." The weakness in such replies is that they concede the principles of the complaints the government has been making. It would be permissible, and in the end rather safer, to insist that only individual

universities can usefully shape their own destiny.

What more robust defence can there be? What British universities should recognize is that there is no reason why the system of higher education to which they collectively belong should be capable both of contributing to the development of technology and of preserving the old traditions of scholarship and research, but that the flaw in the British government's complaints over the past six years is that it is unreasonable to expect that each single institution will contribute in the same way. Constitutionally, the vice-chancellors' committee cannot easily abandon the polite convention that all universities are equal, which is especially crippling when it is acknowledged that the essence of an effective reply to the British government's complaints must be a plea that greater diversity is now, as for decades, the most urgent need. The truth is that British higher education has been made too uniform as a consequence of government policies and the polite conventions of the academic life. Only within such a framework will it be feasible for some universities and polytechnics to make their way in the world by concentrating on the needs of industry and for others to do what they already do well, scholarship and academic research. But will not greater diversity flow from the plan of the University Grants Committee to begin allocating a part of its subvention for universities on the basis of a judgement of the quality of the research which is at present carried out? The first steps in this direction will have been taken six months or so from now. The most obvious danger is that the result will be to strengthen the universities that are already strong, and publicly marking out the others as second-rate, undeserving of more than basic support and thus incapable of self-improvement.

Budget

The impending row about this discriminatory allocation of money is only one of the several novel crises now facing British universities. Another is the continuing decline of the budget, estimated to be shrinking still at between one and a half and two per cent a year when allowance is made for increased costs and the difficulty of settling salary increases within the government's national allowance. The University Grants Committee has said that it will not be long before it is forced to recommend that one or more institutions should be closed, but that it will not shoulder the invidious task of saying where the axe should fall. That crisis could come sooner rather than later, perhaps as early as next May. Then, to round out the sense of gathering gloom, the function of the grants committee itself is being reviewed. The excuse is a minor reference in a report on the efficiency of universities published earlier this year, but it seems unlikely that the committee appointed for the purpose will constrain itself within a framework of accountancy. The ideal is that the review should settle on principles for supporting all kinds of higher education, polytechnics as well as universities, and should then work out a way in which the grants committee can function more as a monitor of success or failure than as a source of funds. But who will say what is success? On last week's showing, the vice-chancellors are not up to the job. Nor, by the evidence of this year's green paper, is the British government. Might that not be the lasting function of a grants committee with a broader membership? □

Crossing the water

France and Britain now seem bent on building a physical link. Will it really happen?

THE bids announced last week by the consortia wishing to build a physical link between Britain and France have been widely predicted and are, as far as they go, staid and safe. The Channel Tunnel Company, which already owns a number of holes in the ground and beneath the seabed on the English side of the water, is understandably bent on building a tunnel, a rather better one than that abandoned in the early 1970s. Others are variously concerned to build a bridge the whole way across this turbulent 21 miles of water, or to span just over half of it with bridge-like structures that then disappear beneath the sea in a stretch of tunnel that will allow shipping to pass without hindrance. The tunnel, which would accommodate only trains, is the cheapest project (at roughly £2,500 million). The bridge-tunnel plan is roughly twice as expensive; building a bridge the whole way across (with an accompanying railway tunnel with which to placate the nationalized railway systems on each side of the Channel) works out at half as much again. The only certainty about what will happen next is that the governments of France and Britain will decide on the scheme to be allowed to go ahead, but that the construction costs will have to be met by private interests, banks and the like.

So has the time arrived when the future of the Channel tunnel link will be laid to rest? Most probably not. For the best part of two centuries, schemes to build a Channel link have been canvassed enthusiastically and, then, as suddenly abandoned. The fear that Napoleon might be able to march an army through a tunnel brought the first wave of enthusiasm to a halt. Now, not even fears of cultural invasion can upset the case for building a link of some kind across the Channel, which is crudely economic. All the bidders now in the market for the attention of their governments base their arguments on the assumption that the cross-Channel business will be worth £500 million a year or so by the time that a tunnel or a bridge is built. If the estimates of cost now put forward are anything like correct, each of the schemes should be economically viable at some point in the 1990s. But how likely are the planners to be proved correct? And what will happen if their estimates are seriously in error, and if the project chosen in the next few months runs into trouble, geological or financial, in the succeeding years?

Whatever the two governments may say, they cannot wash their hands of some kind of responsibility for whichever project they choose. From the start, they will be intimately involved, as governments, in the renegotiation of navigation rules between France and Britain. And on each side of the Channel, the project will need planning permission on a scale that only governments can provide. Then, in reality, there is no chance that either government could turn its back if a project turned sour after a few years. At the very least, it might be necessary to dismantle a few surplus structures in the centre of a busy international waterway. But the political pressures that would apply to government that decided it could abandon a physical link half-way through construction would be irresistible.

That is one reason why there is the strongest case for the two governments to face the responsibilities they will not be able to escape now, and not to wait until the project is under way, with money committed. It is right and proper that they should expect the bulk of the funds required for the project to be raised from private sources, but it would help to give the project solid foundations if the two governments were to become minority shareholders in their own right. Then, if the worst came to the worst, they would be in a position to decide whether to step in to mount a rescue for a faltering project or to continue to stand aside.

Meanwhile, it remains to be seen which project will be chosen. Given their mutual interests in the prosperity of railways, both governments have a vested interest in the rail tunnel, but this should be suppressed. The high economic value of the

traffic between Britain and France, and the pace at which it is growing, shows that the trade transcends the narrow interests of the railway industries. To be able to drive across as well as go by train should be the objective, whence the case for the hybrid bridge and tunnel at the very least. The misfortune in all this, however, is that so little has been done to implement what is obviously the best of all ways of crossing the Channel, the scheme for putting the clock back to the late Pleistocene, when lots of people crossed from France to Britain, and building a dam across this narrow strip of water, nowhere more than 120 feet deep. □

No tin-pan alley

The International Tin Council, an international cartel, is in trouble. The surprise is the delay.

Two weeks ago, the London Metal Exchange was thrown into chaos by the announcement that the gentleman called the buffer stock manager of the International Tin Council had run out of money. Trading in tin was promptly suspended, and has not yet been resumed. Meanwhile, commodity brokers in the City of London, used as they are to skating on thin ice, are worried sick by the prospect that some of them may not be able to pay the debts they have incurred over the past several months in buying and selling tin. Even the British government, in its avuncular role as the custodian of the last resort of the reputation of the City for honest dealing, is alarmed that the reputations of people and of institutions may be so damaged that people elsewhere will not use London as a place in which to buy and sell metals and other commodities. (London has a virtual monopoly on metal-trading.) The several causes of the tin crisis have by now been well catalogued. Improbably, they range from the illicit activities of poachers based in Singapore who have been dredging tin from the deep waters of Malaysia to the cupidity of the tin-producing countries, which have done everything they can to keep up the retail price of tin, including the curious practice of buying back through the Tin Council roughly a third of all the metal their producers have been able to sell. Collectively, the tin producers and their customers have been united through the International Tin Agreements, by whose terms the International Tin Council exists, in an attempt to ensure that water runs uphill. In the past few days, the natural laws have reasserted themselves.

Nobody should be a whit surprised. All along, the objective of the Tin Council has been to stabilize the price of tin. The buffer stock manager has instructions to buy the metal when the price falls below a certain value (fixed periodically) and to sell when the price exceeds another value. In between, however, he is neutral, sitting on the stocks he has accumulated. Although the United States has remained stolidly outside the tin agreements, other consumers have over the years benefited almost as much as the tin producers. Prices have indeed been stable, much more than might be expected in a market in which the balance between supply and demand can fluctuate enormously. The trouble is that, as in the petroleum market, stability means different things to producers and consumers. In tin, the chief producers, among whom Malaysia is the most important, have naturally taken the view that stability is not worthwhile unless it also implies a high price, just over £8,000 a tonne when trading was halted ten days ago. But the industrial demand for tin has shrunk as the many importers of this expensive metal have learned to use others instead. In retrospect, it is clear that the buffer stock manager should have blown the whistle earlier, and that he should not have waited until he ran out of credit with the banks to whom the tin market now owes the best part of £600 million. Rarely can the buffer stock have grown as consistently as in the past few months. But the diagnosis is easier after the event. And now, when nothing is sure except that a great many people and banks will be left holding a large quantity of tin they do not want, the lesson to be learned from this discreditable episode is that the laws of supply and demand are not safely defied. □

AIDS

Politics of premature French claim of cure

THE French physician who claimed last week a dramatic improvement in patients with acquired immune deficiency syndrome (AIDS) when they were treated with the immunosuppressant cyclosporin A now says he was pressed into a premature press conference by an over-enthusiastic minister.

"It wasn't our decision — it was the ministry of health's", said Dr Philippe Even of the Laennec Hospital in Paris. Dr Even agrees that the announcement of results after a week's trial with six patients, without controls, was "premature", but claims it was the pressure and the enthusiasm of health minister Mme Georgina Dufoix that led to the press conference. Dufoix appeared on television to claim this was "a great French discovery" that "bears the label of France".

Even is now following the line of his critics, saying that what is needed now is a full-scale trial. Ironically, it was his request to the ministry for help in setting up a trial that led to the widely-condemned public announcement.

Nevertheless, Even says, the treatment of his key patient, a 38-year-old man acutely ill with "end-stage" AIDS, has been "really dramatic". This person had been the most seriously ill of six patients treated, by last Friday, for nine days with the drug. The patient has shown a 100-fold increase in the population of T-4 (T-helper) cells, the white blood cells specifically infected by the AIDS virus. Now the man has a T-4 cell count of 400 per cubic millimetre, against 4 previously. Having been comatose and bed-ridden, he is now walking and feeding himself.

Dr Even also claims that "something very curious" happened during treatment indicating that cyclosporin A has a genuine effect. The patient, who had been taking cyclosporin orally got diarrhoea on the sixth day of treatment which interfered with absorption. His T-cell count immediately dropped, so that Even and his colleagues Jean-Marie Andrieu and Alain Venet decided to administer the drug intravenously. "Immediately his T-cell count rose again", says Even.

The five other patients, all less acutely affected, had shown at least a doubling in T-cell count since treatment to levels of more than 300 per cubic millimetre (against a healthy level of some 700–1,200).

Even's explanation is that cyclosporin A halts the activation of T-4 cells but does not inhibit the production of new T-4 cells by the bone marrow and the thymus gland. The result, says Even, is that mature T-4 cells can be held in check while

the immune system regenerates itself. Even says that the activation of T-4 cells is "pivotal" in the replication of AIDS virus and the development of the disease; he speculates that an occasional course of cyclosporin A might keep the disease in check or even, with luck, eliminate it.

Outside France, AIDS clinicians say that the premature release of results was not only improper but cruel: "some of our patients will clutch at anything". There is also a fear that cyclosporin A could in the long run actually exacerbate the disease. According to one leading immunologist, the drug alone mimics the immunosuppressive effects of AIDS itself. There are also cases of AIDS-antibody-positive renal transplant patients who were put on immunosuppressants subsequently developing more acute AIDS than patients who had not been immunosuppressed, it is pointed out in London.

Moreover, the rise in T-4 cell count seen in Paris appears too rapid to be explained by regeneration of lymphocytes by the

bone marrow, a process that might be expected to take 3–4 weeks, rather than just nine days. Further, the cerebral infections seen in AIDS patients, perhaps mimicking the infections of sheep by visna virus, may be resistant to cyclosporin A. London immunologists point out. The target cells for the HTLV-III/LAV virus of AIDS in the brain have not yet been identified, and may not be controlled by cyclosporin A even if it crosses the blood/brain barrier.

But Dr Even says that not one in five of the population of new T-cells in the patient's blood is an immature T-6 cell from the thymus, indicating that cyclosporin A has stimulated the production of new lymphocytes, at least from the thymus gland.

The next step, says Even, will be the setting up of a multi-centre trial of cyclosporin A in acute patients in France and, later, of an international trial. The pharmaceuticals company Sandoz, which makes and markets cyclosporin A, is convening an international conference on 8 November at its Basle headquarters in Switzerland, to prepare just such an international trial. But the only North American delegates attending will be Canadian, Even says. So far there are no delegates from the United States, and therefore no apparent US interest in joining in a trial. "That is their decision", Even says.

Robert Walgate

SDI

Star wars critics criticized

Washington

THE US Congress's Office of Technology Assessment (OTA), no stranger to controversy over President Reagan's Strategic Defense Initiative (SDI), has run into yet another dispute on the subject. Dr Robert Jastrow, an independent authority on missile defence, and Dr Frederick Seitz, chairman of the Defense Science Board, last week protested that the majority of an OTA advisory panel that supervised a recent OTA report* on SDI (see *Nature* 26 September, p. 276) were "strongly opposed" to SDI, and that OTA staff were biased against the project.

One of Jastrow and Seitz's chief complaints is that the OTA advisory panel, of which Seitz was a member, did not vote to endorse the report, and that there was no outside review. OTA's report concluded that SDI will increase national security only if the project achieves great technical success and if the Soviet Union cooperates in a negotiated arms reduction. Peter Sharfman, OTA's international security programme manager, replies to the criticism by pointing out that OTA's advisory panels never vote on staff reports and that their function is to provide independent review.

The Jastrow/Seitz attack on OTA was made at a briefing held by the Heritage Foundation, a conservative think-tank with strong links with the Reagan adminis-

tration. Seitz was recruited to the advisory panel after General Daniel Graham, a strong advocate of SDI, had resigned, also alleging bias. Sharfman rejects categorically the charge that a majority of the panel were "strongly opposed" to SDI, and denies the suggestion that OTA staff were stretched beyond their limits.

Apart from the procedural issues, Seitz and Jastrow say that OTA failed to take account of numerous technical advances in missile defence in the past year. In their view, progress has been so encouraging that key demonstrations of SDI technology might be feasible 10 years sooner than was expected, with deployment possible during the 1990s. Among the advances named are the free electron laser, electromagnetic railguns and a new type of rocket engine, SCRAMJET.

OTA replies that it was familiar with the technological advances but avoided giving performance details because they are classified; all the technologies mentioned by Seitz and Jastrow, excluding SCRAMJET, are described in the OTA report. And in reply to a criticism that OTA overestimated the effectiveness of Soviet countermeasures, OTA says it regrets that specific technical objections were not raised by the advisory panel before the report's publication.

Export controls

Scepticism over liberality promise

Washington

THE US Department of Commerce (DoC), long the bugbear of US high technology exporters because of its allegedly inefficient processing of export licence applications, is to make substantial changes in its licensing regulations. The changes are required by recent legislation and by agreements reached with the United States' partners in COCOM, the Coordinating Committee on Multilateral export Controls*.

Most recently, the department has been advertising to industry the virtues of its new "foreign availability office", intended to ensure that the United States does not restrict on national security grounds exports of high technology items that are freely available to the Eastern bloc from other sources. But, logical though this sounds, industry is sceptical of whether the office will have the desired effect.

Foreign availability was supposed to be taken into account in determining whether to allow exports even before the Export Administration Amendments Act became law on 12 July, but requests for licences on these grounds usually fell on deaf ears. The new office is intended to change that. William Archey, assistant secretary for trade administration, has described the new foreign availability rules as "the dark horse" of export regulations.

Under the new act, after receiving an export licence application that rests on a claim of foreign availability, DoC will be allowed a grace period of 18 months during which time the US government can seek to "negotiate away" the foreign source of the item in question. The exporter has to establish that the item is available in comparable quantity and quality from a foreign source, but the burden of proof will now lie with DoC if it seeks to reject the applications. Even then, DoC may not be able politically to allow the export of some items demonstrably of foreign availability. Yet, even if the cynics are right, the office may still benefit industry in other ways.

Bill Maxwell, of the Computer and Business Equipment Manufacturers' Association, believes that the new office will probably succeed in preventing items being added unnecessarily to DoC's "commodity control list" of proscribed items, even if it does not manage to remove any already there. And that could be significant, especially with increasing sophistication of electronic equipment manufactured in some other "Pacific rim" countries.

The United States has consistently made the running in efforts to restrict the flow of Western high technology equipment to the East. Last year, DoC turned down licence applications for \$300 million worth of exports for which orders had been received, on the basis of pre-licence

checks and intelligence reports. But the United States unilaterally controls exports of some items that are not controlled by its major trading partners, which has frequently led to quarrels with allies.

One especially sensitive issue has been whether contracts legally entered into can subsequently be terminated for foreign policy reasons by invoking export controls. Despite lobbying by allied governments, nothing in the new act alters the presumption of extraterritoriality. The new act will nevertheless make it slightly harder for the President to terminate contracts for foreign policy reasons. He has to testify that the controls are necessary, and that a failure to act will lead to a "breach of the peace". (What exactly constitutes a breach of the peace is left undefined. The resulting loophole is "big enough to drive a truck through", according to one independent specialist.)

Among COCOM's more significant achievements was the agreement last year to decontrol exports to the Eastern bloc of many less-capable computers, on the grounds either that they were unlikely to be of military use or that control was impractical. COCOM merely has to be notified when exports of this sort are planned, and DoC has recently introduced regulations to allow such exports from the United States to COCOM member countries without a licence.

But if the decontrolled items will reduce DoC's workload, other changes required by the new act will increase it. DoC has been given tight new timetables for processing licence applications: 15 days for exports to COCOM countries and 60 for most others for which COCOM review is necessary (down from 90). The timetables will benefit US exporters — if they are met.

Walter Olson, deputy assistant secretary for trade administration, says the United States is "pleased" by progress in COCOM, although he notes there are still areas where the United States and other members do not yet see eye to eye.

Disputed items include certain kinds of software, particularly that used in designing and fabricating semiconductors. But Olson hopes that further progress will be forthcoming, especially now that COCOM has changed its cycle of operations so that one quarter of the entire (secret) proscribed list will be reviewed each year, rather than there being a complete review every three or four years. The result, he says, will be that DoC will be able to keep effective controls on those items that need to be safeguarded, while ensuring that some of the complaints that have been heard in the past about US manufacturers hobbled by harsh export controls are not repeated.

Tim Beardsley

* COCOM member countries are the United States, the United Kingdom, France, Belgium, Italy, the Netherlands, Luxembourg, Norway, Denmark, Canada, West Germany, Portugal, Greece, Turkey and Japan.

Texas keeps on bidding for collider

Washington

COMPETITION among states to play host to the proposed Superconducting Supercollider (SSC) has led to questions in Congress about design assumptions even before a complete conceptual design has been drawn up. When the central design group announced in September its choice of magnet design for the accelerator, most people thought the question had been settled. The group chose a high-field cos θ design over a competing superferric design (see *Nature* 26 September, p.277). But Representative Joe Barton (Republican, Texas) has now carried out his own study, and concludes that the design team made a mistake.

Both designs employ superconducting magnets, but where the high-field cos θ design relies on the arrangement of the current-carrying wires to produce a uniform magnetic field, the superferric design relies partly on steel pole pieces to shape the field and return flux efficiently. The superferric magnet design is cheaper per foot, but because it produces a lower-strength field more magnets are needed. One important factor in a choice between the two designs is the cost of tunnelling, which depends on the terrain.

The superferric design would lead to a

larger SSC with a circumference of 100 miles, as opposed to a modest 60 miles with high-field magnets. Texas would be ideal for SSC, especially if the larger version were to be built, for the state has sites where tunnelling costs would be low. Last week, at a hearing in the House of Representatives on prospects for high-energy physics, Mr Barton told Maury Tigner, head of the design group, that "it could be shown that" the superferric design would lead to a cheaper SSC. Tigner hotly disagreed, offering to debate with Barton, point by point, on the magnet selection panel's analysis. Barton said he might submit some written questions.

With Congress in a deficit-cutting mood, winning a commitment to build SSC will be difficult. The US high-energy physics community last week brought in big guns from Europe to help make their case, in the form of Herwig Schopper, director of CERN in Switzerland, and Carlo Rubbia, at present at Harvard University. Present estimates of the cost of SSC, a 40 TeV proton-proton collider, range from \$3,000 to \$6,000 million. The design group should complete its conceptual design study in April, when more accurate cost estimates should be possible.

Tim Beardsley

Plant engineering

Gene transfer makes a start

Savannah, Georgia

ONE reflection of the rapid growth of plant molecular biology is that it is now possible to attract some 1,800 participants to one of those unwieldy international symposia whose concurrent sessions occupy the ballrooms of the larger hotels in out-of-season resorts. The International Society for Plant Molecular Biology at any rate regards its congress held here last week as a milestone in the field.

Although the use of recombinant DNA to transfer genes between plants may eventually change the face of the Earth, to judge from last week's scientific presentations, its principal impact in the immediate future is likely to be on the fortunes of the agrichemical industries that support much of the basic research. Only two weeks ago, a team from Calgene reported (*Nature* 317, 741; 1985) the introduction into a tobacco plant of a bacterial gene conferring resistance to the Monsanto herbicide glyphosate; similar results were reported here by Rob Fraley (from Monsanto's own laboratories working in collaboration with Nam-Hai Chua and colleagues at Rockefeller University), but with a plant gene and in tomato as well as tobacco and petunia.

Glyphosate is an indiscriminate herbicide that destroys crop plants and weeds alike, and whose use is therefore confined to ground clearance. Glyphosate tolerance into crop plants would thus greatly extend the application of the chemical.

But this is not the sole, or probably even the principal, reason for the impressive advances in the manipulation of herbicide resistance. Analogous experiments were reported by Lawrence Bogorod (Harvard) with a gene for the Ciba-Geigy herbicide atrazine, which is now out of patent and so no longer of compelling commercial interest. The attraction is that the genetic and biochemical basis of herbicide tolerance is both relatively simple and extremely well understood. Most broadly desirable genetic assets, such as the ability to resist pathogens or fix nitrogen are complex and relatively ill-understood. In pathogen resistance, pathogens seem capable of producing virulent mutants about as fast as molecular biologists can engineer plants to resist them. Herbicides are an easier target.

Among other sobering considerations offered in a presentation by M.S. Swaminathan, director of the Institute of Rice Research in Manila, is that the basic genetics of Third-World staples such as rice are in such a primitive state that they have simply not been accessible to molecular manipulation. A further difficulty is that rice, like other cereals, is a monocotyledon. So far, the recipes for regenerating complete plants from manipulated cells will work only for dicots, whence the con-

centration on tobacco, petunias or, at best, tomatoes.

Nevertheless, the Rockefeller Foundation is supporting a campaign on the rice genome which, with the use of the molecular mapping techniques that have been so successfully exploited in the analysis of human genetic disease, should be reasonably well charted within a year or so. Progress on regenerating genetically engineered plants is less predictable (tissue culture is still largely a black art) but two speakers at Savannah reported a significant step forward. Genes artificially introduced have not in the past functioned stably in cultured cells from monocotyledons, but this has now been achieved in maize (Michael Fromm, Stanford) and Italian rye grass (Lawrence Potrykus, Friedrich Miescher Institute). The next step is to persuade the cultured cells to

regenerate into a complete plant, which many believe will be a matter chiefly of luck and patience.

Meanwhile, new techniques for gene transfer based on electroporation (which allows DNA to enter cells exposed to strong electric fields) are helping molecular biologists to identify and isolate the genetic control elements that determine the responses of plants to the critical features of their environment. The DNA elements that enable genes to be activated by heat and light have already been identified; Jim Peacock reported that his group at the Commonwealth Scientific and Industrial Research Organization in Canberra now has a gene that controls the induction of others in anaerobic conditions. In principle, these genetic control elements could be manipulated to increase the resistance of crops to natural disasters such as drought. How it will be in practice, and when, it is too soon to guess. Even resistance to herbicides is not yet ready for the field. **Miranda Robertson**

Space insurance

Market confident of survival

Washington

US GOVERNMENT intervention to provide emergency insurance cover for commercial space ventures would be disastrous. Witnesses from the National Aeronautics and Space Administration (NASA), insurance companies and satellite manufacturers all agreed on this point when telling Congress last week how to prevent a space insurance crisis; more than \$600 million has been lost by insurers in the past 21 months, threatening the much vaunted commercialization of space.

James Barrett of Intec (International Technology Underwriters) is confident that market forces will prevail and allow the insurance industry to continue to "facilitate, but not subsidize" commercial space projects. He suggests spreading the load of space insurance risks throughout many smaller companies, which could support an "insurance pool" dedicated to space shuttle launches and cargoes. He also feels that the manufacturers should take more of the risk for the functioning of their products, which would doubtless improve reliability. Barrett is opposed to the sort of competition that is occurring at the moment between Arianespace and NASA; because Arianespace provides guaranteed launch insurance at below-market rates, NASA is planning to offer cut-price relaunches to customers whose satellites have failed within a given timespan. Such deals will deprive the insurance industry of premium revenue and inhibit the spread of risk, according to Barrett.

Jack O'Brien, NASA's general counsel, agrees that the market will stabilize without government intervention. NASA

already helps its smaller customers by waiving liability for small self-contained payloads so that the only loss the experimenters face is the face value of the project. NASA also disallows claims against each other by participants in a particular flight, and includes itself in this ban. It is carrying out a further evaluation of its risk allocation policies, but wants to find a solution in conjunction with the insurance industry that does not open the door for government regulations.

Predictably, the manufacturers themselves do not want to be liable for any loss risk. Charles Schmidt of RCA Astro-Electronics says that the fiercely competitive business leaves no room for such guarantees. Smaller companies would lose business if a "no insurance, no financing" policy were introduced. One compromise would be for the industry itself to form a last-resort pool.

The message to the government from the construction industry and the insurers alike is clear — the market will look after itself. The satellite industry was so successful in the first ten years of its existence that insurers have grossly underestimated the cost of risks, leading directly to the present crisis. Underwriters are convinced that the pendulum will swing back and that a stable compromise can be reached if the government will give them time. In a country where space is taken so seriously that the normally conscientious chairman, Bill Nielson (Democrat, Florida), of the committee taking last week's evidence was absent because he is in training for the next shuttle flight, the commercial space industry had better make sure it has reason for its confidence that a solution can be found. **Maxine Clarke**

Japanese conservation

War on war on migrating birds

Tokyo

JAPAN may not have much of reputation abroad when it comes to protection of wild life. But inside the country, conservation groups are growing stronger. In the coming weeks, volunteers from the Wild Bird Society of Japan will be taking to the hills in force to try to prevent the mass netting of migratory birds.

During middle to late November, migrating birds pour into northern Japan to escape the Siberian winter. In olden days, many were netted out of sheer necessity;

the farmers of the northern provinces were poor and the birds provided one of the few sources of protein in winter. Now that Japan is an advanced technological power, poverty has disappeared and there are not many people left in the bird netting business. But advanced technology has also made it possible for a few people to catch an enormous number of birds.

Nowadays, Japan makes the world's finest mist nets — light, strong and so fine that they are invisible to the bird's eye — and plenty of inexpensive audio systems that can be used to broadcast recorded bird calls. The result is that flocks of thousands of birds may be drawn into a large net and captured at one time. Those most frequently taken are *tsugumi* (dusky thrush, *Turdus naumanni*), *kashiradaka* (rustic bunting, *Emberiza rustica*) and *atori* (brambling, *Fringilla montifringilla*). Last year alone it is estimated that more than four million birds were killed and mostly sold to restaurants. And as a thrush can fetch as much as 1,000 yen (nearly US \$5) it is a profitable business. Recently it has attracted the interest of criminal gangs.

The setting of mist nets has actually been illegal since 1947, but as there is no restriction on their sale and fines for illegal taking of birds are small, the law has had little effect.

Increased concern for wild birds is now beginning to make inroads into the poachers' takings. The membership of the Wild Bird Society of Japan has increased

seven or eight times since the end of the 1970s to its present 16,000. This year, for the first time, volunteers from the society will patrol the hills all through the key November weeks, searching for illegal mist nets. If any are found, the evidence is guarded and the police called.

The society would like to take things a step further and ban manufacture of mist nets altogether. That would please environmental groups in Italy and Spain which are fighting a mass capture of migrating birds in their own countries. Mist nets are imported from Japan. The Environment Agency, which has been pressing local governments to crack down on the poachers, is also backing a ban on mist nets. But the agency lacks regulatory powers and has yet to move the ministry responsible, the Ministry for International Trade and Industry (MITI). So far, MITI has tended to take the manufacturers' side, for a variety of rather spurious reasons, including the possible effect of a mist net ban on the hair net industry.

Alun Anderson

New Soviet guidelines

THE new draft programme of the Communist Party of the Soviet Union, the first since 1961, includes not only a strong commitment to scientific and technical progress, but also a code of conduct for scientists.

The party, it is stated, "supports the bold quest, the rivalry of ideas and approaches in science, and fruitful debates and discussions". Contraindications for science therefore include: scholastic deliberations, the passive recording of facts without drawing bold generalizations, jumping on bandwagons, and severing oneself from reality. In view of the complex and interconnected nature of current problems, a deepening of the links between the natural, technical and social sciences is required. Forms of organization of science should be developed that will facilitate interdisciplinary study of topical problems and the necessary mobility of scientific cadres. The structure of scientific institutions and of research and development procedures must be made more flexible.

An "essential condition for the progress of science", it is noted, is the constant influx of fresh forces, including forces from the production sector, and the skilful utilization of scientists' creative potential.

Finally, and tacitly admitting that ideology is not enough to get and keep Soviet research working at full capacity, the programme specifically urges the provision of financial incentives for scientists "depending on their real contribution to the study of theoretical and applied problems".

French ceramics

Plans for silicon carbide fibres

HERMES, France's answer to the US space shuttle, will be made of ceramic composite, and will thus avoid the sticky tiles that caused complications in the early days of the US craft. At least, those are the plans of Société Européenne de Propulsion (SEP), the company charged with preparing the curved nose, leading edge of the wings and underbody of Hermes, the parts that will face re-entry temperatures of up to 1,600 degrees centigrade for periods of some 20 minutes.

SEP has chosen for the task one of its most advanced ceramics, consisting of silicon carbide fibres bonded into a sintered silicon carbide matrix: "a kind of ceramic concrete", according to one British ceramicist. A major problem with such materials is to produce curved forms, and Hermes is of course full of aerodynamic curves. But SEP has been working on similar composites, including carbon-carbon matrices, for a decade, and has already produced trial curved silicon carbide/silicon carbide sheets some 50cm-1m across. This is a long way from the many metres required for Hermes sheets, but SEP reckons it has another ten years to develop the technology. If all goes well with the development, the ceramic will be more than mere cladding and will act as a structural part of the craft, although it may need support from more conventional stress-bearing structures underneath.

Meanwhile, according to M. Roger Lesgards, president of SEP, the company's first priority will be to establish French independence in the supply of the silicon carbide fibres, which at present come from Japan. SEP intends investing jointly with the French chemicals giant Rhône Poulenc in a factory to produce the fibres and the composite. SEP did the same with carbon fibres a year ago, in setting up a factory near Lyons to manufacture the fibres in concert with the steel company Alsthom Atlantique.

Lesgards describes SEP as having a "really good position" in the world market for high thermal resistance composite ceramics. Japan asked SEP for samples of the silicon carbide/silicon carbide matrix, says Lesgards, and the US Department of Defense is interested in using the material for missile nose-cones. The composite is already in use as brake disks for Formula One racing cars, and is also being tested for use as vanes to direct the thrust of rocket motors.

SEP foresees three possible world markets for the material. The first, requiring production levels of a few tonnes per year, would be a market for space and military uses. The second, raising the market tenfold, would be in aeronautics (for example, in turbines). The third and largest,

involving another tenfold increase, would involve uses in diesel motors and other common equipment, which could raise demand to a few hundred tonnes a year. Lesgards estimates.

The material is costly to produce, but economies of scale could reduce cost tenfold at the highest market levels. Lesgards predicts. With this in mind, SEP recently entered into cooperation with the German diesel engine manufacturers MAN to develop ceramics for diesel motors, with support from French and German government agencies.

SEP also plans to extend its international cooperation to work on ceramic turbines with companies in Norway, Sweden, Spain and Italy, if support is forthcoming from this week's ministerial meeting on Eureka at Hannover. Under Eureka, SEP has put forward a plan for a FF 200 million (£18 million) research programme on ceramic turbines. The company has also proposed the development of a commercial demonstration ceramic diesel engine (FF 100 million) and two varieties of ceramic turbine (FF 100 million each). SEP would be happy if half of the total FF 500 million were supported by governments or banks, Lesgards says. **Robert Walgate**

British nuclear research

Harwell goes half-private

In the UK Atomic Energy Authority (AEA), 1 April 1986 is known as Vesting Day. This is Civil-Service-speak for the day on which AEA ceases to be a division of a government department and becomes a "trading fund", equivalent in status to that of a limited company in which the British Treasury is the only shareholder. Among other things, the authority will thus be able to lend and borrow money on the open market. The Treasury will set financial targets, and there will be high hopes on the government side that the authority will be able to generate a surplus.

AEA's largest establishment, the research laboratory at Harwell in Oxfordshire, is also the best placed to profit from the new regime. A year ago, an encouraging 33 per cent of its research was supported by non-governmental contracts, but now the figure is nearly 60 per cent.

To continue at its current level of activity, Harwell needs funds totalling £100 million a year. From next April, there will no longer be a subvention from the De-

partment of Energy (DoE) to cover research carried out on behalf of government departments and other parts of AEA. Instead, separate contracts will be negotiated to cover each research programme — including fast reactor research, fusion research and work on thermal reactor and general safety research. It does not follow that the individual contracts will together compensate for the lost lump-sum contribution, the two being calculated in different ways, which is another stimulus for Harwell to look further afield for contracts.

Recent investment in the facilities at Harwell should help in the push for more outside contracts. A new radiochemical handling laboratory has been built, based on experience gained at Los Alamos in the United States and at Karlsruhe and Jülich in West Germany. The five high-integrity concrete cells can contain any combination of alpha, beta and gamma radiation. Each cell is ventilated separately so that a chemist measuring, say, a caesium isotope in one cell need not fear that someone else's experiment is generating just that activity at the other end of the containment area. Experiments are set up in large stainless steel boxes, or "cassettes", before being hoisted into the containment cell on cranes.

The new laboratory was opened last week by Sir Frederick Dainton, on his last day as chairman of the National Radiological Protection Board. The date was chosen to mark an anniversary of sorts — 40 years ago, on 29 October 1945, Prime Minister Clement Attlee announced in the House of Commons that Harwell, a disused airfield near Didcot, was to become Britain's first nuclear research laboratory.

Main customers for the new facilities will be British Nuclear Fuels Limited, the Central Electricity Generating Board, other AEA divisions and Amersham International, the radiochemicals company spun off from AEA several years ago. Although the company is now branching out into the increasingly popular field of non-radioactive assay kits, Amersham's isotope business is still large, and will be an important part of Harwell's plans, managed through Amersham's own offices on the Harwell site.

While Harwell can contemplate a future of at least the same level of activity as now — provided that in the long term it is able to adapt to the changing needs of industry — some other AEA divisions have fared less well in recent government reviews. Spending on fusion research at the Culham laboratory, for instance, is to be reduced by £1 million, £2 million and £3 million in three successive financial years. However, support for the Joint European Torus (JET), also sited at Culham, is not affected. **Charles Wenz**

New Soviet space agency is formed

THE Soviet Union has established a new space agency to make use of space research results in the national economy. The existence of the Main Administration for the Creation and Use of Space Technology for the National Economy and Scientific Research (*Glavkosmos*) was revealed last month in an unremarkable middle-page interview in *Izvestiya* with the new agency's head, A.I. Dunaev. This reticence is all the more remarkable because, when the Soviet press daily castigates President Reagan's strategic defense plans, *Glavkosmos* might have been used as evidence of the more peaceful Soviet approach to space.

Reticence, however, seems to be the keynote of *Glavkosmos*. The interview does not reveal when it was established, only that it "has been set up and has started working". Dunaev, however, refers to all its activities in the future tense, suggesting that it is a very recent innovation. Dunaev's own identity, too, remains obscure. Nothing is said of his career or academic qualifications, his background or even his given name and patronymic.

Even the purpose of *Glavkosmos* itself remains obscure. Dunaev notes the benefits of space research to the Soviet economy; long-distance communications (including the simultaneous printing of Moscow newspapers in Siberia and the Far East), meteorology, land-resources survey, navigation and the international "Kosmos-Sarsat" air-sea rescue system as well as the production of new superpure and biologically active materials aboard manned spacecraft. But his list reads like a

summary of the Soviet presentation at the United Nations conference on the peaceful uses of space (UNISPACE-82) three years ago.

Within the Soviet Union, the main purpose of *Glavkosmos* seems to be administrative. A number of ministries and government departments, Dunaev said, are concerned as are scientific organizations.

A special coordinating body is now needed, and *Glavkosmos* will have charge of the planning and space projects for the collection and dissemination of space information for practical purposes, and will also be responsible for Soviet participation in international cooperation programmes, both the Comecon "Interkosmos" project, and broader programmes such as the current *Veha* (Venus/Halley) probes in which nine countries are cooperating.

Whether *Glavkosmos* will be responsible for Soviet manned programmes is unclear. Dunaev's reference to future long-term stations is part of a general outline of space plans, not of the specific functions of his agency. Also unclear is the relationship of *Glavkosmos* with the Space Research Institute of the Soviet Academy of Sciences, which so far has acted as coordinator for the transmission of space data to the production sector.

Glavkosmos will not, it appears, be responsible for research planning, and its creation seems merely to interpose one more body between research and production. But it is precisely here that endemic delays in the transmission of results occur.

Vera Rich

Soviet computer education

Teething troubles galore

SOVIET plans to introduce computer studies in the senior forms of every school throughout the Soviet Union may be delayed by up to six years, according to the Uzbek historian, U. Mannanov, a member of the joint commission on information science and computer technology. Launched by a resolution of the Council of Ministers of the USSR and the Communist Party central committee in March, the plan was one of the first major decisions of the Gorbachev era, and was widely acclaimed as the next significant step in implementing the "scientific and technological revolution". Computer studies were already operating on a pilot scale in Soviet schools, but the essential feature of the new plan was its universality — every school was to have microcomputers, and every 15- and 16-year-old would learn how to use them.

Fifteen pairs of blue jeans and a personal computer.....?

From the beginning, there seemed to be some doubt as to whether the hardware would be ready in time. At the end of March, the director of the Institute of Teaching Content and Methods of the USSR Academy of Pedagogic Sciences, Professor Vadim Monakhov, admitted that the choice of computers to install would be determined by availability, not suitability. In the event, many schools failed to get their computers and, when the new term began in September, were informed that they would have to teach "theoretical" computer studies until the hardware arrived. At the same time, leading articles in *Pravda* hailed the introduction of universal computer studies as a major advance in the building of a truly science-orientated society, implying that the delay in installing the computers was a fairly short-term one. Mannanov's revelation of the likely length of delay was made only in *Pravda Vostoka* (Eastern Truth), a provincial newspaper not normally available in Moscow.

Another problem is a shortage of teachers able to teach computer studies. During the vacation, summer schools were organized for the physics and mathematics teachers who would be taking the new courses. According to Mannanov, of those attending the courses

in the Uzbek SSR, 92 per cent had previously never seen a computer.

Although the logistic problems of computer education are obviously worse in the Soviet Union, where editions of textbooks (and now of software packages) have to be envisaged in editions of 4 million, several Comecon countries seem to be experiencing similar difficulties. Poland, with barely a thousand computers in schools, has declared a moratorium in practical computer education for at least two years. Even so, it seems that a large number of pupils are already computer-literate, either from official youth club facilities or through access to "privately acquired" Western computers, of which there are thought to be between 25,000 and 60,000 in the country.

Czechoslovakia, on the other hand, in

spite of an admitted 40 per cent shortfall in deliveries of computers to secondary and vocational schools, has declared computer education one of the two major priorities for the current academic year (the other is peace studies). In Bulgaria, one of the main producers of computers in the Comecon bloc, not all schools even in the capital, Sofia, have their own computers, and some use facilities which properly belong to the higher education sector.

Only in Hungary does computer education seem to be running to schedule. The Hungarians, moreover, seem more aware than many of their Comecon partners of the broader applications of classroom computers, so that during his visit to Britain last month, the Hungarian minister of education and culture, Dr Bela Koepecsi, particularly requested a visit to a secondary modern school where computers are used not only in the mathematics and science classes but also in the humanities.

Japanese psychiatry

Hospital reforms under way

Tokyo

THE first steps towards reform of Japan's mental hospitals were taken last week with the publication of a new set of guidelines by the Ministry of Health and Welfare. Criticism of the way hospitals are run has been mounting for some years but the ministry showed little reaction until visits from human rights organizations, including the International Committee of Jurists (see *Nature* 316, 571; 1985), stimulated international criticism.

The chief aim of the new guidelines is to give patients in mental hospitals the right to communicate with the outside world. The almost total isolation of mental patients has been seen as a major factor in allowing recent abuses to take place. At the Utsunomiya Hospital, where violence was regularly used against patients and two were alleged to have been beaten to death, patients tried to communicate with the outside world by launching paper aeroplanes. Earlier, an incident at an Osaka hospital where a patient was beaten to death by hospital staff came to light only through the chance discovery of a message from one of the patients. He had written the message on a piece of paper, wrapped it around a stone and thrown it out of the hospital grounds.

Three new provisions are made: public telephones will be installed in closed wards and patients will be free to use them as they wish; patients will be allowed to correspond with anyone they like, including lawyers and human rights groups; and staff will not be present when visitors are received, unless specifically invited. Furthermore, it is recommended that the telephone numbers of human rights organizations be freely displayed.

Critics are far from satisfied: they point

out that the new guidelines are just guidelines and fear they will not be obeyed. They also stress that loopholes exist: communication can be limited if required for medical treatment or protection of patients, while letters may be examined if there is any suspicion that patients might, for example, be trying to send drugs out of the hospital. The only counter to possible misuse of these clauses is that any restrictions placed on patients must be entered on their medical records.

What many groups pressing for reform would like to see are the kinds of changes requested by the International Commission of Jurists, chiefly the setting up of a completely independent review tribunal that would have the right to inspect mental hospitals and to which patients would have right of appeal. At present a patient may be committed to a mental hospital by the superintendent of a mental hospital once the guardian's consent has been obtained and patients have no rights to demand independent medical evaluation. This problem may be tackled in a reform of the Mental Health Act promised by the government for next year.

Whatever legal changes are made, there will remain the difficulties of effecting the changes in attitude that lie at the root of the problem. Although a reform movement exists, and a small number of "half-way houses" and workshops have been set up to help patients back into society, the mentally ill remain outcasts. A quarter of the patients in mental hospitals do not receive even one visit a year. And as many as half the patients could be released from the hospitals if their families were willing to have them back. It is these attitudes that will eventually have to be tackled.

Alun Anderson

Research in Ecuador

Universities are squeezed

Quito, Ecuador

THE Galapagos Islands, long a symbol of ecological diversity and evolutionary theory, also symbolize the relative strength in Ecuador of the biological sciences, blessed both by rich natural resources on their doorstep and by government support.

Dr Tjitte de Vries, director of the biology department at Quito's Catholic University, manifests the optimism born of sufficient funds. Each of the three government agencies that support research supports one of his projects (in the highlands, the tropical rain forest and the Galapagos). Moreover, his grant from the Canadian Wildlife Service to study the effect of pesticides on the peregrine falcon exemplifies the flow of foreign aid into biological research in Ecuador. "If a scientist has the initiative", says Dr de Vries, "the money is there", both for equipment and the high logistic costs of working in the rainforest.

The most important governmental agency for university research is El Consejo Nacional de Universidades y Escuelas Politecnicas (CONUEP). Of the 7,000 million sucres (100 sucres=US\$1) distributed in 1985 from the Ministry of Finance to the 17 universities and polytechnics, 500 million sucres were assigned to research. Some research contract work is handled as well by El Consejo Nacional de Ciencia y Tecnologia (CONACYT), but research in the Galapagos is supported by the Charles Darwin Foundation, whose resources come from a mixture of government and foreign sources.

In 1984, CONUEP accepted 97 projects from 13 universities, out of 248 applications. There were as many applications in 1983, but only 25 were supported. Winning government aid depends on doing research in a priority area, as defined by El Consejo de Desarrollo (CONADE) in the National Development Plan 1984-88. Preference is given to projects in health and nutrition, agriculture and technology.

Researchers in Ecuador seem cheerfully to accept government-imposed directions for science. There is no secret about the priorities, which many feel are justified for Ecuador's development. For example, Dr Joan Llauger, head of the chemistry department at the Catholic University, shows no regret at leaving his speciality in metallurgy and concentrating on nutritional questions such as the oxidation of vegetable oil. The government has no history of giving funds to research, explained Mr Juan Maldonado, head of the Charles Darwin Foundation, so researchers have not yet come to consider such aid as their right rather than privilege.

Ninety per cent of government aid flows through the state universities, so the assets of the five private universities are particularly squeezed. Even in Dr de Vries' de-

partment, the highest degree offered is between a US bachelor's and master's. More infrastructure, says Dr de Vries, is necessary to reach international parity, primarily in libraries (the Catholic University cannot afford *Nature*), equipment, field stations and computer facilities. Fields dependent on expensive equipment, such as physics, are much harder hit. The physics department at the Catholic University only prepares teachers; it does no research. Dr Ernesto Cadena of that department says that even though a medical physics graduate programme has been started with foreign aid, there are not enough good physics teachers in high schools, no money for research laboratories, and few jobs for physicists in Ecuador.

Students interested in a higher degree are often encouraged to go abroad and then return to work. Dr de Vries, who is Dutch, came to Ecuador with UNESCO. Two members of his staff got doctorates in the United States, one in Germany, and another received a master's degree in Italy. Some of his students are on fellowship in Britain, the United States and Brazil.

The lack of tradition of research on an international level is the worst problem. Dr Llauger says he invites foreign professors to lecture and presents papers abroad every year, but that few of his colleagues (far fewer than in biology) do likewise. Few universities require publication from the professors.

The plethora of universities in such a small country is itself a doubtful boon. According to Dr Gonzalo Cevallos, who has taught economics at Quito's Central University and now works for the oil firm Intrade, the philosophy of free education has resulted in every town wanting a university. There are no entrance requirements, only a small percentage graduate, and few of these can find jobs.

"Ciencia aplicado" that augments the country's productivity is a clear government priority over basic research. Governmental entities perform much of this work, though, according to many, they are merely applying foreign techniques

rather than pursuing applied research. Funds from the state budget (for 1986, 201,000 million sucres) flow through the various ministries to institutes and government companies, which, says Dr Cevallos, do "research in brackets". INIAP, for example, is an institute under the Ministry of Agriculture that does plant research such as in cross breeding, and CEPE is an oil company controlled by the Ministry of Natural Resources and Energy. The military also has applied research arms: its Geographical Institute, for example, does topographical research, primarily mapping.

The techniques and equipment used by these institutes and companies, if not actually developed in Ecuador, are often the most advanced available. The Geographical Institute uses both US LANDSAT and French satellite facilities; the oil industry uses three-dimensional seismic technology; and the forestry department is importing a tissue culture laboratory to clone trees.

Oil and its byproducts are a primary source of funds for Ecuador's development. Because of its reliance on oil to support government projects and pay off foreign debt, Ecuador will not abide by OPEC's quota of 184,000 barrels/day and is instead nearing 300,000 barrels/day. Even in oil, says Dr Cevallos, it is more economic to use foreign techniques than to try to catch up to international levels of expertise.

Oil also helps to support the growing commitment in Ecuador to learning about the country's environment and how to use it wisely. According to Mr Maldonado, the government has accepted the foundation's advice on resource management, as evinced by an increase in support from an average of 70,000 sucres in 1964-66 to 10-15 million in 1966-85. Sixty wardens have been added to the national park system this year; the peasants are asking for reforestation projects; and a research station in the Amazon basin is studying how to raise alligators, fish and guinea pigs without destroying the forest. Ecuador and Costa Rica, says Dr Roque Sevilla, director of the National Forestry Programme, are the most advanced countries in this part of the world in terms of ecologically sound resource development.

Applied science is then, finally, paramount in Ecuador. That can be explained by the government's "practicality" and the need to spend money elsewhere.

There is another, darker possibility, however. Fear is spreading that the government, backed by banking and manufacturing interests, plans to strangle the universities, which are seen as catalysts of anti-government activity. One commentator says that recent increases in university research funds are nothing in the face of 35 per cent inflation: the government, a democracy only since 1979, "is out to crush the Left with no holds barred".

Elizabeth Collins

NERC studentships

SIR—Keith Runcorn (19 September, p.196) has obviously cogitated carefully over the report of the Natural Environmental Research Council (NERC) committee chaired by me which reviewed methods of allocating research studentships, since his letter appeared nearly a year after the report was published. His views are reminiscent of some of the evidence we received from heads of departments (possibly a slight majority), but which were opposed by a majority of other members of staff and by virtually all the students themselves. Our conclusions were not entirely maverick; we advertised our review as widely as we could and had about 400 comments from academics, employers, students and other research councils about the most equitable and positive ways of allocating studentships. Our recommendations were based on assessing all the information we had, giving appropriate weight to the relevance of the suggestions and criticisms.

It is of little general interest to respond to all the misapprehensions accumulated by Professor Runcorn. Perhaps the drafting of our report was obscure. But five points need making:

(1) The committee consisted of three Earth scientists, two former research council secretaries with backgrounds in the biological sciences (Sir John Gray of the Medical Research Council and Sir William Henderson of the then Agricultural Research Council, both of whom had overseen allocation procedures very different from that used by NERC), and myself, an ecological geneticist. We examined the past and present methods used by all five British research councils, and other possibilities suggested by our respondents. We were unanimous in our recommendations, and our report was endorsed by the NERC Council.

(2) Professor Runcorn opines that "the ratio of geophysical to geological studentships is too small both for scientific advance and for national needs". This is an appropriate and fashionable prejudice for a geophysicist to hold. The underlying problem is that it is extremely difficult to determine the proper allocation of studentships between disciplines. If demand is any guidance, requests in the NERC area for life science studentships are much greater than for Earth science ones. My committee recommended an "in-depth independent study with a view to laying down guidelines for the distribution of available awards between the (subject) committees", and this has been accepted by the NERC Council.

The general and very important problem of forecasting "national need" was analysed by a White Paper on Postgraduate Education (Cmd 6611, 1976) which expressed the view that "it is unlikely that a close match between supply and demand

could ever be achieved and it will be important to resist the temptation to forecast and plan with spurious precision". Sir Peter Swinnerton-Dyer's ABRC Working Party (1983) reviewed past endeavours on the subject and concluded that all these "attempts at manpower planning (for the supply of scientists and technologists) foundered principally on an uncritical faith in the economic contribution of education and on a confused concept of demand. . . since there are many PhDs whose working career has borne little relation to the subject of their thesis however potent the contribution of research training has been to their intellectual and practical development. It remains a truism that the quality of highly trained manpower is as significant as its quantity."

(3) Professor Runcorn repeats the accusation raised originally by the heads of university zoology departments that membership of a NERC committee improves the chance of getting a studentship project approved. If true, this would be worrying. The fact is that some committee members are more successful than expected in some years and less successful in others. There is no consistent picture, but (as Professor Runcorn notes) NERC "Council takes a very serious view (of this). . . important area which will be carefully monitored in the future". There need be no mystery or suspicion here: if the most active and productive research workers constitute the grants committees, they would be expected to obtain a higher than average proportion of awards. Perhaps the key factor is that the grants committees are not self-perpetuating cabals: for some time NERC has been inviting university departments and individuals to nominate to the committees, and this invitation was repeated in the committee's report. For the record, five of the 18 members of NERC's current geological sciences training awards committee are geophysicists.

(4) Professor Runcorn wants NERC to abandon its "effortful, cumbersome, expensive and unsatisfactory scheme". Ignoring his fourth adjective, our published response to this comment was that "as each research studentship costs in excess of £17,000 and represents three very important years of a student's life, the expenditure of a supervisor's time (in preparing an application) is fully justified".

(5) However, I suspect that the crucial difference between Professor Runcorn and my committee is over the purpose of a research studentship. We firmly and explicitly rejected the idea that a PhD student should be primarily a research assistant involved in an ongoing research project. Professor Runcorn quotes disparagingly "NERC's statement of the primary objective of a research studentship". Our understanding and conclusions were

based on two clear objectives. I am unrepentant about these:

"The primary aim of Council's policy must be to enable the intellectually most able graduates to receive the best possible training. An essential part of this training is the preparation of a PhD thesis, which also provides a means of ensuring that research undertaken is preserved and can be made available to others. Within the context of research training, it is council's aim to influence the quality of training and its direction and content.

"The second main objective of council's policy can be defined as ensuring that there is an adequate supply of manpower trained at postgraduate level to meet the national requirement in the sciences most closely concerned with the natural environment.

"A very important consequence of research training, even though incidental to that training, is the major contribution which research students make to the research output of universities. In itself, provision of training awards is a major contribution to the research community."

I am not clear why Professor Runcorn is so dismayed by our report. As a scientist, he cannot logically complain about an exercise that examines all relevant data and then excludes inadequate conclusions from it (even if he does not like the positive solutions that emerge). If it is any comfort to him, I was not allocated a NERC studentship this year, despite the fact that I put forward two *excellent* proposals to the grants committees. . .

Human life

SIR—The distinction between dependently viable protoplasmic life and independently viable organismal life (respectively at the level scale of the molecule and of the individual), as made by R. C. Hoult (*Nature* 8 August, p.480), is quite correct, although it does not follow that the life quality necessarily attributable to a fetus *in utero* is that of protoplasmic life only.

The fetus has undoubtedly an organismal life, and we can speak of "fetal behavioural states" (*Prenatal Diag.* July 1985, p.269) in spite of its dependence on its mother for energy supply. An infant seems not to differ very much in this respect. It must be recalled that, up to the onset of implantation, the human conceptus is "free living" in the sense that it is not attached to the mother in any way. Nor can I see how a human adult individual during parenteral nutrition could lose his "human life" or organismal quality.

ATRIAL NATRIURETIC FACTOR

Now available: Radioreceptor assay kit for the measurement of physiologically active ATRIAL NATRIURETIC FACTOR in human plasma with the following features:

SENSITIVE:

detection limit is less than 10 pg/ml in plasma (normal levels ~ 100 pg/ml)

SPECIFIC:

no cross-reaction with biologically inactive forms of ANF or other hormones.

ACCURATE:

alpha-hANF is fully recovered

PRECISE:

intra- and interassay variability better than 10%

CONVENIENT:

assay simple to perform within 2-3 hours

EXPERIMENTAL AND MOLECULAR PATHOLOGY

EDITORS: F. Coulston, W.A. Thomas
MANAGING EDITOR: K.T. Lee

Experimental and Molecular Pathology presents articles on disease processes in relation to structural and biochemical alterations in mammalian tissues and fluids, and on the application of the newer techniques of analytical chemistry, histochemistry, pharmacology, toxicology, and electron microscopy to problems of pathology in man and animals. Articles are drawn from such scientific areas as virology, endocrinology, immunology, nutrition, chemotherapy, and geographic pathology. Studies on the mechanism of action of drugs, vaccines, and pyrogens, among other topics, when related to alterations in tissue, are also included.

Volumes 44-45 (1986), 6 issues (including annual subject index)

JOURNAL OF ULTRASTRUCTURE RESEARCH

EDITOR: F.S. Sjöstrand

Journal of Ultrastructure Research publishes papers concerned with the ultrastructural organization of biological material as analyzed by means of electron microscopy, X-ray diffraction techniques, X-ray microscopy, and polarization optical analysis. The journal features papers on experimental work, particularly that dealing with correlation of biochemical and structural properties. Articles on techniques and instruments that are of importance for the development of the field as well as descriptive works on newly discovered structural components are also presented.

Volumes 94-97 (1986), 12 issues (including annual subject index)
Annual Subscription Rates
In the U.S.A. and Canada: \$384.00
All other countries: \$437.00 U.K. only: £324.00

EXPERIMENTAL NEUROLOGY

EDITOR: C.D. Clemente
MANAGING EDITOR: L.H. Marshall

Experimental Neurology is an international journal devoted to basic experimental research in the neurosciences. Articles reporting experimental data from clinical research pertinent to fundamental neuroscience principles are considered.

Volumes 91-94 (1986), 12 issues (including annual subject index)
Annual Subscription Rates
In the U.S.A. and Canada: \$392.00
All other countries: \$459.00
U.K. only: £340.00

PROCEEDINGS OF THE SOCIETY FOR EXPERIMENTAL BIOLOGY AND MEDICINE

EDITOR: M.R. Nocenti

For more than 80 years, *Proceedings of the Society for Experimental Biology and Medicine* has been disseminating the results of investigative research in biomedicine. Recently, in direct response to the needs of the journal's readers, the Editorial Board increased the range of topics and added new features. The journal now features special invited articles, minireviews, and rapid communications, in addition to regularly submitted articles. The more inclusive coverage, strengthening the journal's interdisciplinary nature, makes *Proceedings* an essential tool for researchers.

Volumes 181-183 (1986), 11 issues (including annual subject index)
ISSN 0037-9727
In the U.S.A. and Canada: \$97.00
All other countries: \$125.00 U.K. only: £93.00

All orders and subscription payments should be sent to: Society for Experimental Biology and Medicine, P.O. Box 151, Cooper Station, New York, New York 10276

EXPERIMENTAL CELL RESEARCH

EXECUTIVE EDITORS: N.R. Ringertz,
T. Caspersson, T. Gustafson, D. Mazia

The chief purpose of *Experimental Cell Research* is to promote the understanding of cell biology by publishing experimental studies on the general organization and activity of cells. The scope of the journal includes all aspects of cell biology, from the molecular level to the level of cell interaction and differentiation.

Volumes 162-167 (1986), 12 issues (including end of volume subject indexes)
Annual Subscription Rate: \$792.00
U.K. only: £587.00

DEVELOPMENTAL BIOLOGY

An International Journal Published under the Auspices of the Society for Developmental Biology

EDITOR-IN-CHIEF: P.J. Bryant

Developmental Biology publishes original analytical research on mechanisms of development, differentiation, growth, regeneration, and tissue repair in plants and animals at the molecular, cellular, and genetic levels.

Volumes 113-118 (1986), 12 issues (including semi-annual subject and organism indexes)
Annual Subscription Rates
In the U.S.A. and Canada: \$792.00
All other countries: \$887.00 U.K. only: £657.00

The virtues of single atoms

Success in cooling single atoms to millikelvin temperatures, and then of trapping them for seconds (or even hours) on end, will benefit not merely spectroscopists but the rest of physics.

THE obvious benefits of being able to study single ions or even atoms are those that the spectroscopists have been extolling for several years, ever since it seemed probable that finely tuned lasers might be used to rob moving atoms of velocity in a specific fashion. Earlier this year, there was a flurry of excitement with the first demonstration that sodium atoms can be "cooled", or robbed of velocity, by the selective absorption of photons (and thus momentum) of a suitable frequency. (The technique and the consequences were fully discussed by B.W. Petley in a *News and Views* article on 27 June this year, p.716.)

Especially because it is now possible to trap electrically charged particles in suitably configured static electric and magnetic fields, the spectroscopists have had plenty to look for, not least the chance to trap small numbers of ions in excited states so long-lasting that the radiation they emit is neither made fuzzy by the Doppler effect, a consequence of movement, nor broadened substantially by quantum considerations, Heisenberg's uncertainty principle in particular. The notion that suitably prepared trapped atoms may make more convenient standards of frequency (or of time) than the more familiar atomic clocks of caesium is not entirely out of court.

But even before these opportunities have been exploited, the hunt seems well under way for a technique for trapping neutral atoms and molecules in apparently empty space. The first informal report of success in this direction came from Harold Metcalf of the State University of New York at Stony Brook (also in *Nature* on 27 June, p.717) hinting at experiments by his own group and by another at Bell Laboratories in which neutral sodium atoms had been successfully trapped for periods of time measured in seconds. Now it seems that more systematic ways of achieving these objectives are in sight.

The article by R.V.E. Lovelace, C. Mehanian, T.J. Tommila and D.M. Lee, all of them from various parts of the physics enterprise at Cornell University, is not so much the report of a discovery as a challenge to other experimenters. They explain that the goal they have set themselves theoretically is to define the circumstances in which it would be possible to trap atoms of neutral hydrogen and then to explore the question whether such an assemblage could ever be made dense and cool enough so as to undergo the

Bose-Einstein phase transition expected of all bosons, particles (in this case atoms) with integer spin (zero included).

Will the challenge be taken up? A glance at Table 1 on p.31 will show how formidable a task lies ahead. At 0.1 degrees above absolute zero (or at 0.1 K), it would be necessary to compress hydrogen atoms dealt with singly to roughly the density expected from molecular hydrogen gas at normal temperature and pressure. Doing this in a vacuum will require a substantial magnetic bottle. But how can such a device, familiar enough in the manipulation of some plasmas which are candidates for thermonuclear fuel, be made to function for atoms which have no electric charge? The clever trick that Lovelace *et al.* describe entails exploiting the potentially different orientations in a magnetic field of the nuclear and electron spins of single hydrogen atoms. It should be possible to trap those atomic arrangements in which both the nuclear and electron spins are parallel to an external magnetic field by exploiting their tendency to congregate at the places where the field is greatest. The snag is that collisions between atoms would require that the experiment would be feasible only at a temperature of 0.0001 K, thought still to be unattainable. Whence the neat proposal that an oscillating magnetic field should be superimposed on a static field in such a way as to create an oscillating magnetic bottle to pump atoms with different hyperfine structure to different regions.

It remains to be seen whether the scheme proposed by Lovelace *et al.* can be exploited as they suggest, but the fact that the scheme has arisen at this stage is a proof of how far the physics of single atoms has developed in the past year or so. Whatever may be the defects of this scheme, nobody would have thought it sensible to put it forward five years ago. And it is also plain that the interest of schemes for trapping single atoms and molecules, or small numbers of them, extends far beyond spectroscopy. B.W. Petley explained in June how measurements of stable confined atomic systems could be used to test the isotropy of gravitational inertia. T. Erber and S. Putterman, on p.41 of this issue, raise another set of questions in fundamental physics that may be answerable by means of atoms and molecules confined in traps. Can such a system be used to test the randomness of the physical processes such as the decay of the

excited state of an atom?

In principle, it might be possible to carry out such a study by means of a single atom or ion that is suitably trapped in a potential well, using some kind of radiation source to excite it and a suitable photomultiplier to detect the photons arising from radiative decay. But the photons used for excitation would have precisely the same frequency as those to be detected by the photomultiplier. If the average lifetime of the excited atom were to be large enough for the intervals between excitation and decay to be measurable, the excitation would be only weakly coupled to the exciting radiation, which would enhance the likelihood that the photomultiplier would be more often activated by exciting radiation than by that from a genuine decay of an excited atom.

So Erber and Putterman propose a neat atomic switch, a way of telling whether a single atom is at any point excited into one of these comparatively long-lived states. To fit the need, the atom must have two excitation levels, one of which is short-lived and the other long-lived. By means of two lasers, one tuned to each of the excitation frequencies, it should be possible to be sure that the atom at any time is in one of three states, the unexcited ground state or one or other of the two excited states. But the amount of time for which the atom is in the short-lived state can be measured by recording the photons arising by the spontaneous fluorescent decay of that short-lived state. Moreover, because the frequency of the transitions in each direction will be high, if the disparity of lifetimes is great enough, when there is no short-lived fluorescence, the atom should be excited into the long-lived state. In other words, the experiment that naturally suggests itself is a means of measuring the length of time for which a single atom persists in the long-lived state.

Erber and Putterman go on to say that these lifetimes, which should be unaffected by any influence of the external observer, should be strictly random numbers. Paradoxically, they remark, the simplest of all physical systems, a single atom caught in a trap, should be more capable than all but the most complicated computing machinery of generating strictly random numbers. The more important point is that the system is yet another way of testing predictions of quantum mechanics. That is another challenge, but increasingly an academic one.

John Maddox

Developmental biology

Mice, mating types and molecular mechanisms of morphogenesis

from Miranda Robertson

Two meetings this year* have marked the arrival of a molecular biology of embryonic development. At both, much emphasis has been placed on the universality of developmental mechanisms in phylogeny. In what follows, I shall use a few selected examples to illustrate the parallels that are being drawn between mice, flies and microbes and to examine briefly what they may mean.

I should state at the outset of this article that the omission of *Drosophila* from its title is not merely a matter of assonance: the dazzling achievements of *Drosophila* molecular genetics have been extensively discussed in earlier articles in these pages and the most recent advances are soon to be the subject of another. I shall therefore mention them only in connection with the arresting discovery that the so-called homoeo-box sequences, comprising part of the homoeotic genes that control *Drosophila* morphogenesis, have highly conserved counterparts in vertebrates (see ref. 1). The hope has been that these sequence homologies may provide one of two new routes to the genes that control morphogenesis in mice and men. The second route that has opened up at much the same time is through the transgenic mouse. DNA microinjected into a mouse embryo will occasionally become integrated into its chromosomes in such a way as to disrupt the normal process of development and thus in principle act as a traceable marker for a gene involved in its control. The work reported by Woychik *et al.* in this issue of *Nature*² has already been publicized³ as a success for the second approach: in a series of experiments in Philip Leder's laboratory in which the *c-myc* gene was injected into mouse embryos, on one occasion the gene fortuitously became integrated so as to produce a recessively inherited deformity of the limbs.

How far can the deformed mouse be regarded as a mammalian equivalent to the homoeotic mutants of *Drosophila*? And how likely is it that the mammalian homoeo boxes will provide a direct route to genes essential for morphogenesis in mammals?

Mice

The homoeo boxes of *Drosophila* are coding sequences of DNA, usually about 180 base pairs in length, first discovered at the 3'-end of the homoeotic genes, mutations in which cause the transformation of one

body part into another. Homologous sequences are found in worms, frogs, mice and man — and in yeast, which seems an embarrassment to their putative role in metazoan morphogenesis (but see later).

Drosophila homoeo boxes fall into two classes (1 and 2), which are about 50 per cent homologous in sequence. But the homology between the homoeo boxes of each class across species is about 80 per cent. At the time of its discovery this was, and is still, the most compelling evidence that the sequence homologies between the homoeo boxes of fruitflies and vertebrates have any functional significance. Other kinds of evidence are somewhat thin. It is now clear that these sequences are expressed in vertebrate embryos, and that their expression is in some cases temporally regulated and tissue specific. Class 1 sequences, for example, are expressed from day 13 in mouse, principally in the dorsal neural tube (Frank Ruddle, Yale); Gail Martin (University of California, San Francisco) finds expression of both class 1 and class 2 sequences between about the ninth and seventeenth days of gestation, and in embryonal carcinoma cells of mouse⁴ and man (Robert Tjian, University of California, Berkeley) class 1 sequences are expressed only after the induction of differentiation.

There is, however, nothing to link any of this with morphogenesis. Nor do mouse genetics provide evidence of anything that might be a homoeotic mutation. There is a morphogenetic mutant (*Tail-short*) that maps near the class 1 homoeo-box cluster on chromosome 11 (see ref. 1); but the association may be entirely adventitious. The mutation induced by *c-myc* in the transgenic mice of Woychik *et al.* may prove more informative.

The principal feature of the limb deformity in the mutant mice is the fusion of some of the distal bones of the limbs, and Leder and his colleagues have been able to show, through genetic crosses, that the mutation is allelic to a natural recessive mouse mutation, *ld*, that also causes bone fusion and maps, like the inserted *myc* gene, to chromosome 2. There is, moreover, a naturally occurring dominant mutation, *Isr*, that maps to roughly the same region and causes the reverse phenotype — bone duplication. The dominant mutation has not yet been shown to be allelic to the recessive; but if it is, the two mutations may reflect, respectively, an excess and a deficiency of a morphogen or growth factor⁵. In principle, then, analysis of the site of the *myc* insertion, which has already been cloned,

should yield the intact gene encoding the factor, and the first identification of an embryonic morphogen.

In practice, however, it has not yet been possible to identify the inactivated gene and Leder's optimism is somewhat guarded, as was the response to his presentation at Cold Spring Harbor. Morphogenetic mutants are not always interesting, as experience with invertebrates has shown. There is for example a *Drosophila* wing-deformity mutant, *rudimentary*, that is simply the consequence of a metabolic deficiency affecting pyrimidine synthesis; and it was repeatedly pointed out that quite non-specific perturbations may disrupt development in an apparently systematic way (this has been a problem, for example, with attempts to apply to vertebrates the technique of specific inhibition of gene expression with anti-sense RNA). It seems unlikely that the fruitfly fraternity will be impressed by mouse geneticists until they can produce a mutant with a perfectly formed paw whose only abnormality is that it ought to have been an ear.

Mating types and mechanisms

In the absence of any evidence of a role for the vertebrate homoeo boxes in the genetic control of development, what might the evolutionary conservation of the homoeo boxes signify? An answer may be suggested by the ostensibly surprising discovery of homologous sequences in yeast — though it is only fair to say that the homology between yeast and metazoan homoeo boxes is of an altogether lower order than those between the metazoan sequences.

It is believed that *Drosophila* homoeo boxes encode protein domains that bind specifically to DNA. It is therefore probably significant that the yeast sequences homologous to the *Drosophila* homoeo box occur in the gene encoding $\alpha 2$ protein, a regulatory molecule that coordinates the expression of genes determining the mating type of yeast cells by binding to a specific sequence in their flanking DNA⁶. It has long been the guiding principle of Ira Herskowitz's laboratory, in which most of the investigations of the $\alpha 2$ protein have been performed, that the control of mating type in the single-celled yeast embodies the fundamental principles of differentiation in higher animal cells. Moreover, yeast mating type has one striking advantage over fruitfly homoeosis: while nothing is yet known about the molecular basis for the homoeotic phenotype, a good deal is now known about the molecular mechanisms that underlie the specification of yeast cell type.

The yeast *Saccharomyces cerevisiae* has two haploid mating types, *a* and α , each of which releases a factor that binds to a specific receptor on cells of the opposite mating type. This causes the two cells to fuse to form an a/α diploid. In *a* cells, the genes specifying the α factor and the *a*-

*The Cold Spring Harbor Symposium on Molecular Biology of Development, 29 May–5 June 1985, and *Nature's* Conference on Genes and Systems in Development, San Francisco, 6–9 October 1985.

factor receptors are silent, whereas those specifying the a factor and the α -factor receptor are active; the converse is the case in α cells; and in a/α cells, both sets of mating-type genes are silent and those that control sporulation, which are silent in the haploids, are activated. Mating type is controlled by a single locus, the mating-type locus *MAT*, which contains an a allele in a cells and an α allele in α cells. The gene products of these alleles are regulatory proteins. Herskowitz and his colleagues have been able to show that $\alpha 2$, one of two products of the α allele, binds to a specific sequence upstream of the a -specific genes and represses them (refs 5 and 6, and Kathy Wilson, University of California, San Diego). The other product, $\alpha 1$ activates the α -specific genes. In a cells, the α -specific genes are silent because of the absence of $\alpha 1$, and the a -specific genes are active because of the absence of $\alpha 2$.

In a/α cells, a completely new pattern of gene expression is generated by the combination of regulatory proteins from both *MAT* alleles. The most recent evidence from Herskowitz's laboratory suggest that the sporulation genes are activated in the diploid cell by repression of *RME1*, a gene whose product inhibits sporulation genes in haploids. The repression of *RME1* requires $\alpha 2$ and $\alpha 1$, which is a product of the *MAT a* allele. Although its mechanism is unknown, the DNA-binding properties of $\alpha 2$ make it likely that an $\alpha 2 - \alpha 1$ complex binds, perhaps cooperatively, to a regulatory site in the *RME1*-flanking DNA. Thus the combination of two regulatory proteins may generate a novel specificity not possessed by either alone. This proposition has been

strengthened by the identification of a presumptive $\alpha 1 - \alpha 2$ binding site whose sequence is related to the known $\alpha 2$ binding site⁷.

Back to mice

How does the molecular mechanism of mating-type determination in yeast help with the two questions with which I began: what is the significance of the homoeo-box homologues, and can transgenic mice provide a mammalian alternative to the homoeotic mutants of fruit-flies? It is not known whether the homoeo-box encoded domain of $\alpha 2$ is directly involved in the binding of DNA, but it is known that mutations in this region abrogate its activity. Since its activity has been shown⁸ to depend upon the formation of $\alpha 2$ multimers as well as on binding to DNA, the homoeo-box encoded domain may be responsible either for binding DNA or for binding between the protein monomers,

It follows that if the conserved homoeo-box sequences do, as seems likely, reflect conserved functions, then it is their binding specificity that is being conserved; but it does not necessarily follow that this binding — whether to DNA or to other proteins — has anything to do with the control of development. There is no dearth of evolutionary precedents for the use of the same highly conserved structure in different physiological pathways: yeast and mammalian *ras* have recently turned out to be a case in point (see ref. 8) and it is a commonplace that a highly conserved hormone may act through a highly conserved receptor to produce a wide variety of unrelated effects in different cells.

What the yeast data may illuminate are the principles on which gene regulation

may work during embryogenesis, rather than the actual proteins through which a particular pattern of regulation is brought about. For example, it is generally accepted that differential gene regulation during development must be controlled in part by signals between cells. Thus it must depend on the temporally and spatially patterned expression by developing cells of the genes encoding the signals and their receptors. Some patterning of this sort is present in microcosm in yeast: in some strains, the a and α mating types (and thus the two factors and their receptors) are expressed in alternate haploid generations, but with the complication that only mother cells may make the switch. The mechanism of this patterned switching is not fully understood but analogous mechanisms may underline patterned developmental switching in higher organisms.

And while changes in gene expression in embryos are not likely to be brought about by the fusion of cells of two different types, it is extremely likely that differentiation is the consequence of varying combinations of cooperating regulatory proteins, as with $\alpha 1$ and $\alpha 2$ of yeast (induction of a new regulatory gene by an extracellular signal could take the place of the fusion of haploid cells in producing new combinations). As it happens, a transgenic mouse recently reported in *Nature*⁹ may provide an approach to the question of novel regulatory combinations in mammalian development. Swanson *et al.* have produced a mouse containing the growth-hormone gene fused to the metallothionein promoter and expressing the fusion gene in selected subsets of neurones in the brain, where neither growth hormone nor metallothionein is normally expressed.

It is traditional in development biology to distinguish between differentiation and morphogenesis. Under this distinction, it is differentiation that is disrupted in the Swanson *et al.* transgenic mouse, and morphogenesis in the Woychik *et al.* mouse. At the molecular level, however, differentiation and morphogenesis have the same mechanism, morphogenesis simply being a consequence of differential expression of genes that control developmental switches. It is the power of the yeast system to show how differential gene expression at a master regulatory locus, such as *MAT*, may give rise to patterns of differential gene expression of the sort that must underlie morphogenesis. □

Angiogenesis

Isolation of a protein that stimulates blood vessel growth

from Lance Liotta

A TEN-YEAR scientific quest to characterize a substance that can stimulate angiogenesis — the growth of new blood vessels — has ended with a triplet of papers in which Bert Vallee and colleagues describe the purification of a protein they call angiogenin and the cloning of its gene¹⁻³. The quest was based on the pioneering work of Judah Folkman who demonstrated that tumour growth requires nourishment by the continual ingrowth of new blood vessels, and suggested that this is the result of a diffusible substance that he termed tumour angiogenesis factor (TAF)^{4,5}. Recognizing the therapeutic potential of an angiogenesis inhibitor, the Monsanto Company provided a \$23 million endowment to Harvard University in 1976 to support Folkman with Vallee, who was to contribute the biochemical expertise necessary for rigorous protein purification. About five years into the research, Vallee and Folkman split their research into independent directions. As a result, Folkman is not associated with the papers on angiogenin, which Vallee considers to be different from TAF.

Folkman and Vallee have used different approaches to the purification of angiogenic substances and this has led to the discovery of two types of purified substance. One is exemplified by a heparin-binding growth factor identified by Folkman's group. Folkman reasoned that angiogenesis begins with the migration and growth of capillary endothelial cells. His group therefore developed the first cloned cell lines of capillary endothelium, and *in vitro* assays to identify and purify factors that are mitogenic for endothelial cells. Klagsbrun and Shing in Folkman's laboratory purified a heparin-binding endothelial mitogen which induces new vessel formation when injected into the rabbit cornea⁶. Subsequently, several groups purified heparin-binding endothelial cell mitogens that are angiogenic⁷⁻⁹. A recent example is the report by Gospodarowicz's group⁷ of two polypeptide mitogens for endothelial cells. The primary structure of one of them — bovine pituitary basic fibroblast growth factor (FGF) — was determined and compared with the amino-terminal sequence of the other — brain acidic FGF. The purified basic FGF is a potent angiogenic substance in chick chorioallantoic membrane (CAM) assays.

Instead of using the endothelial cell as a starting point for purification, Vallee's group has accumulated and used large quantities (2,000 litres) of conditioned medium from human colon carcinoma cultures. The proteins in the medium were

fractionated by cation exchange and reverse phase liquid chromatography, and directly assayed for angiogenesis in the CAM assay. Purified angiogenin has a relative molecular mass of 14,000 and does not bind heparin. Only 3.5 pmol are required to induce blood vessels in the cornea by a mechanism that is apparently unrelated to endothelial migration or proliferation.

It is widely believed that angiogenin and the heparin-binding proteins may be members of a whole family of factors that induce and regulate the growth of new blood vessels; the angiogenesis literature contains many reports concerning a variety of different factors at various stages of purity, all of which can induce vessel growth in the cornea. From one point of view this is expected, since the development of a new capillary network is a complex process involving a number of steps. One of the first steps may be dissolution of the subendothelial basement membrane at the point of endothelial cell outgrowth¹⁰. Subsequent steps include endothelial locomotion, endothelial tube formation, development of capillary loops, renewed establishment of the basement membrane and maturation of the vascular channels^{5,11}. These steps may be coordinated by multiple signals from the endothelium and other host cells in response to the angiogenic stimulus. Angiogenesis may be analogous to the blood coagulation cascade in that one event leads to the next through the action of specific mediators. Although

angiogenin is not the only substance that can induce angiogenesis, it may be a key trigger for the process.

The most significant accomplishment of Vallee's group is the cloning of the angiogenin gene, which turns out to be one of the small number of mammalian genes known that lacks introns. The amino-acid sequence of angiogenin predicted from the gene sequence is strikingly homologous to human ribonuclease, including conservation of the amino-acid residues that are essential for the activity of ribonuclease. The physiological significance of the homology is unclear, since angiogenin lacks ribonuclease activity and ribonuclease itself is not angiogenic. Expression of the gene for angiogenin is probably not limited to tumour cells. Nevertheless, angiogenesis may be more tightly regulated in normal tissues than in neoplastic tissues.

The cloning of the gene for angiogenin now makes it possible to study one potential mode of regulation of angiogenesis. The gene can also be used to produce large quantities of angiogenin so that its mechanism of action can be fully studied. This may ultimately lead to pharmacological strategies for inhibiting or augmenting the growth of blood vessels. Control of angiogenesis could have an impact on human diseases ranging from neoplasia to myocardial ischaemia. □

Palaeontology

Fossil radiography

from Simon Conway Morris

MUSEUM visitors will be familiar with the striking brassy-yellow colouration of many ammonites, the result of replacement of the fossil by iron pyrites (FeS₂). Not surprisingly, this replacement typically involves the hard skeletal parts that provide the stock-in-trade of most palaeontologists. There are, however, extraordinary instances where pyritization may preserve the soft parts and more lightly skeletalized components of animals and plants from the otherwise inexorable processes of decay (Fig. 1). The Lower Devonian Hunsrück Slate (about 400 Myr) of West Germany is widely recognized as one of the most important deposits for soft-part preservation in the fossil record, and on page 53 of this issue

Wilhelm Stürmer describes another major find from this palaeontological gold-mine in the form of a unique specimen of a squid, aptly named *Eoteuthis*.

Stürmer's description is important on several counts. Not only does this discovery extend significantly the geological timescale of the teuthids, but it may ultimately result in a revision of current notions about cephalopod phylogeny, especially for the coleoids (squid, cuttlefish and octopus). At present, because coleoids generally lack preservable hard-parts, there is a lamentable fossil record that is almost entirely derived from Jurassic or younger rocks, and there is little consensus concerning the phylogenetic relationships within the squids and their

Fig. 1 A back-scattered electron image obtained with a scanning electron microscope of pyrite framboids from exceptionally well preserved trilobites with soft parts, from the Beecher's Trilobite Bed, New York State.

relatives.

Eoteuthis is one more addition to the roster of remarkably diverse finds from the Hunsrück, which boasts a wealth of otherwise poorly known forms. Among others, there are trilobites with preserved appendages, pycnogonids and a variety of more enigmatic arthropods, ctenophores, polychaetes, nautiloids, starfish and crinoids (Stürmer, W., Schaarschmidt, F. and Mittmeyer, H.-G., *Kleine Senckenberg-Reihe* 11; 1980). This wealth of fossils, providing the most complete insight into a mid-Palaeozoic marine community, continues to be augmented both by amateur collectors and from Stürmer's private quarry in Kaisergrube.

Stürmer uses sophisticated X-ray equipment and high-resolution photographic materials to produce radiographs of pyritized fossils concealed in the slate (Fig. 2). The density of the pyrite in contrast to the surrounding shale makes radiography particularly suitable, especially if the specimen is largely concealed with the rock. By carefully controlling the conditions of exposure and using image enhancement, formerly obscure structures may be revealed to a resolution of at least 5 μm . His recent descriptions of the Hunsrück biota and of material from other special palaeontological sites (Stürmer,

Fig. 2 Radiograph of a fossil crinoid from the Hunsrück Slate. Also known as sea lilies, crinoids are echinoderms, related to starfish and sea urchins. Only two specimens of this species have been found and this picture has been assembled from radiographs of several species. (Photograph courtesy of W. Stürmer).

W. *Interdisc. Sci. Rev.* 9, 1; 1984) highlight the success of the techniques. They contrast with traditional methods of preparing Hunsrück fossils by mechanical excavation that require utmost care to avoid damaging the gossamer films of pyrite.

The precise conditions governing pyritization in the Hunsrück are still obscure. The preservation of soft-parts, probably by filling cavities or forming coatings, by pyrite precursors such as greigite (Fe_3S_4), probably took place very shortly after burial. This would accord with recent textural and sulphur isotope studies of pyrite paragenesis (Hudson, J.D. *Sedimentology* 29, 639; 1982 and Love, L.G., Coleman, M.L. & Curtis, C.D. *Trans. R. Soc. Edinb. Earth Sci.* 74, 165; 1983), and suggests that this early stage of pyritization could persist only as long as bacterially

mediated sulphate reduction occurred. Interruption of sulphate influx from the overlying seawater, perhaps by rapid sediment deposition, could have arrested the bacterial activity that was presumably contributing to the overall biodegradation. But this hardly explains the selective replacement of the Hunsrück organisms, or the scarcity of similar fossil occurrences. Another example is the celebrated Beecher's Trilobite Bed in the Upper Ordovician of New York (Cisne, J.N. *Palaeontograph. Am.* 9 (53); 1981). Perhaps the rarity is more apparent than real and surveys of other fine-grained sediments will yield some surprises.

Nuclear physics

Pions still pose problems

from Philip J. Siemens

A REPORT¹ that pi mesons, or pions, have been produced in collisions of complex atomic nuclei accelerated to only 23 per cent of the speed of light has added to the problems of nuclear physicists trying to explain pion production in low velocity nuclear collisions. Simple predictions based on the idea that pions result from collisions between individual pairs of neutrons or protons fail to account for pion production at such low collision velocities and the hope is that the phenomenon will reveal new details of nuclear structure.

Since each nucleus will normally exist in its state of lowest energy, a pion cannot be removed without supplying sufficient energy to provide not only for the pion's kinetic energy of motion, but also for the energy mc^2 associated with its mass m . The same amount of energy would also be sufficient to create a new pion that had not been part of the original nucleus.

The more usual way of liberating pions from nuclei (or creating them — the two processes cannot be distinguished) is to bombard nuclei with accelerated projectiles such as neutrons or protons; the kinetic energy of the accelerated particle produces or liberates a pion when it strikes the nucleus. Starting with a knowledge of how pions are produced in collisions between individual neutrons or protons, theorists have been able successfully to predict features of the production of pions from complex nuclei, such as how often they are produced and their distribution in energy and angle. These predictions are based on the idea that a pion is created when the projectile — which may be a photon, electron or pion, as well as a neutron or proton — strikes one of the neutrons or protons in the target nucleus; the resulting pion may either escape or be reabsorbed by the nucleus.

The difficulties start when complex nuclei are used for projectiles as well as for targets. In the past few years, new accelerators have been commissioned that are able to accelerate complex nuclei, such as carbon or neon, to speeds where the total kinetic energy of the nucleus is sufficient to create a pion, whereas the kinetic energies of the individual neutrons and protons are too small for the purpose. Although pions are seldom produced in these collisions — as rarely as once in a hundred million collisions — they have been observed, initially in 1979 at the Lawrence Laboratory in Berkeley, California². Surprisingly, the pions were produced from beams of nuclei with a velocity of 0.43 c , whereas the minimum velocity necessary to produce a pion from a neutron or proton striking a target of protons is 0.64 c . In 1982, an experiment³ at CERN in Geneva produced pions from nuclear beams with a velocity of 0.4 c and the following year⁴ the National Superconducting Cyclotron Laboratory in East Lansing, Michigan yielded pions from beams of a velocity of only 0.27 c . This downward trend is continued by the 0.23 c reported by Oak Ridge National Laboratory in Tennessee⁵. Experiments in progress at accelerators at Caen, France and at Texas A&M University in the United States may continue the trend.

Because the pions observed in these experiments cannot be produced by collisions of individual pairs of neutrons or protons, they ought to reveal information about the structure of the nucleus as a whole. Two theoretical models have been partially successful in interpreting the observations. The first model, by Jorg Aichelin and George Bertsch of Michigan State University⁶, explains the number of pions by assuming that the projectile and

target fuse together, distributing the projectile's kinetic energy throughout the combined nucleus in the form of heat. Applying statistical mechanics, this model gives a good account of the pions' energies for the faster beams but cannot explain why their average kinetic energy does not decrease as the beam velocity falls below 0.35 *c*. Below this speed, the pions' kinetic energy distribution seems to retain a high temperature, even though the excited nuclei that emit them are cooler. The model also makes no prediction about the angles at which the pions are emitted.

To explain the angular distributions of the pions requires quantum mechanics, because the wavelength of their matter waves is larger than the size of the nucleus that emits them. So far, the only applicable quantum theory has been developed by Walter Greiner, Berndt Mueller and co-workers at the University of Frankfurt. This model draws on an analogy with the emission of electromagnetic waves: the deceleration of the nuclei as they collide provides a time-varying current which causes radiation of pionic matter-waves. This theory gives a reasonable account of the angular distribution⁶ but predicts —

contrary to experiment — that no pions will be emitted in collisions of carbon beams with carbon targets, since carbon has zero isotopic charge (the pionic analogue of the electric charge). An *ad hoc* modification of the theory would permit a reasonable reproduction of the data but would fail at still lower energies, where it would continue to predict pion emission even when the total energy is insufficient.

The theorists' inability to understand the cooperative mechanism of pion production in low-velocity nuclear collisions has not discouraged the experimenters from competing to lower the velocity even further. Since pions are the main agents of the strong forces that hold nuclei together, theorists hope that the data will eventually provide a better understanding of nuclear forces. □

Geology

East Asian tectonic collage

from A.M.C. Şengör

As the accompanying map shows, Asia consists of numerous continental and oceanic fragments stitched together by continental collisions. These not only enlarged the continent, but also disrupted parts of it through collision-related rifting and strike-slip faulting, as may be seen in the current convergence between India and Eurasia¹. During the last decade China has emerged as an ideal place to study the processes of continental collision and evolution of orogenic collages²⁻⁶, offering a tremendous variety of collisional mountain belts that are now in, or were fossilized at, different stages of their evolution. Two papers in a recent issue of *Nature*, by Mattauer *et al.*⁷ and Peltzer *et al.*⁸ deal with the tectonics of one of China's most important mountain ranges, the Qin-Ling Shan — "the backbone of China proper"⁹.

Since the time of the expeditions of P. Armand David in 1866, Count Bela Széchenyi from 1877 to 1880, and especially Baron Ferdinand von Richthofen from 1868 to 1872, the Qin-Ling Shan has attracted the attention of geologists. The unravelling of how and when eastern Asia was assembled is critically dependent on the tectonic evolution and timing of collisions along this belt, but even the establishment of the age of the main deformation has been no easy matter. Mainly on the basis of von Richthofen's observations, Suess¹⁰ described it as a orogenic belt of medial Carboniferous age, whilst

Argand¹¹ saw in it a 'Hercynian chain' with pre-Devonian enclaves. In the first detailed study of the chain in 1929, Chai and Huang⁹ revised von Richthofen's stratigraphy and moved the age of the main orogeny into the Jurassic. Later, in his now-classic 1945 memoir¹², T.K. Huang pointed out that recent research had established the age of the Qin-Ling Shan as "pre-Jurassic". Although Huang left open the possibility of a late Palaeozoic ('Hercynian' as he called it) deformation, he strongly favoured an Indonesian (late Triassic) orogeny. During the last two decades, opinions on the age of the main orogeny along the Qin-Ling Shan have varied from Devonian (400 Myr) to late Triassic (210 Myr), with the majority of the Chinese and foreign authors favouring an Indonesian orogen with a polycyclic history stretching through the 'Caledonian' and 'Hercynian' cycles¹³⁻¹⁸.

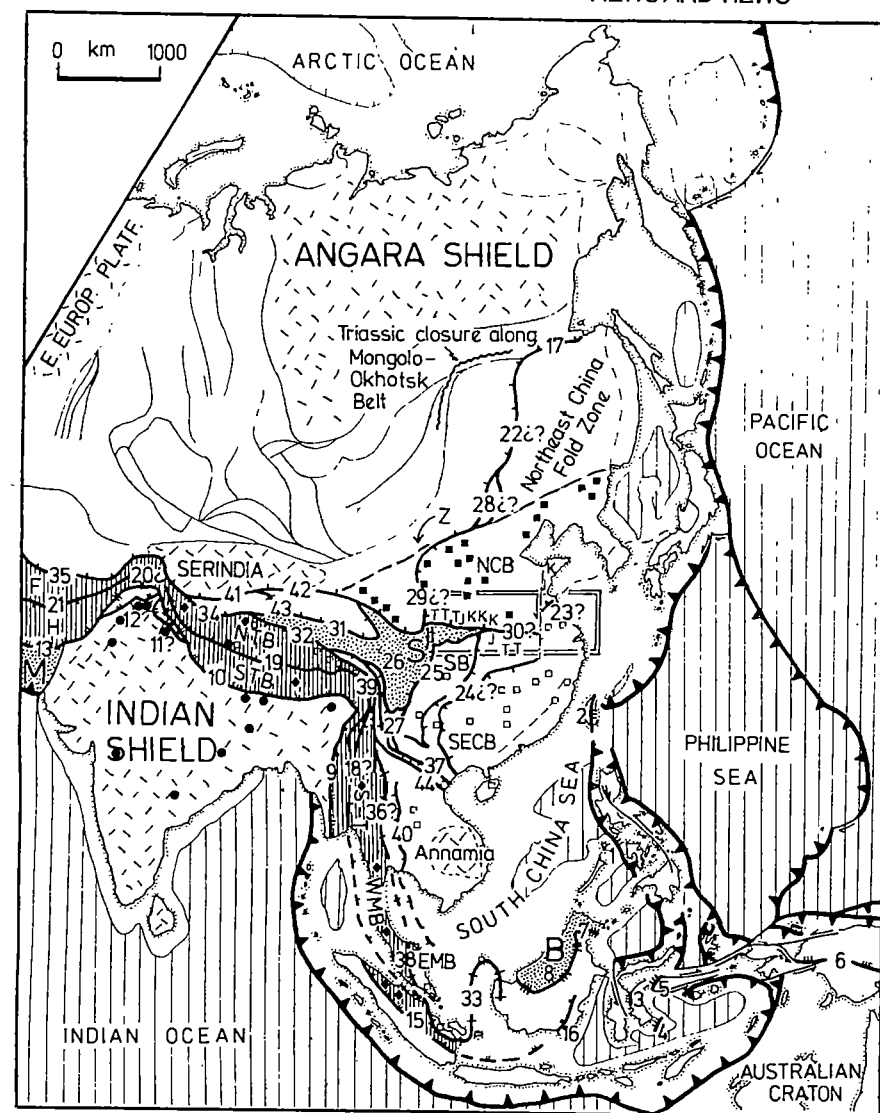

Mattauer *et al.*⁷ divide the Qin-Ling Shan into five longitudinal zones characterized by distinct rock assemblages and separated by major steep faults. In zones 1 through 4 (from north to south) they recognize a 'Caledonian' collision belt (an unfortunate feature of the paper by Mattauer *et al.* is the employment of obsolete and misleading Stellerian phase nomenclature that they seem to have inherited from their Chinese sources), and in the most southerly zone 5 they see an Indonesian intracontinental fold and thrust belt. They

also recognize a 'Hercynian' deformation and metamorphism in zones 2 through 4, that are also viewed as intracontinental, that is, post-collisional.

The implied view that the North and South China block had already collided by the Devonian represents a minority opinion even among Chinese geologists and conflicts with other evidence from palaeobiogeography¹⁹ (see figure) and palaeomagnetism^{20,21}. In my view, the geological map provided by Mattauer *et al.*⁷ does not contain cartographic evidence for a Devonian or even a late Palaeozoic collision along the Qin-Ling mountains (for instance, there is apparently no unconformable molasse of appropriate age nor any intrusion earlier than late Palaeozoic cutting the structures discordantly). Because the available evidence in the published literature overwhelmingly favours a Triassic collision^{4,13-20}, I obtained an independent opinion from K.J. Hsü, who had visited the same area as Mattauer *et al.* earlier this year under the guidance of Chinese geologists.

Hsü believes that the Qin-Ling Shan could be interpreted as a collision-type mountain belt, comparable to the Alps, that culminated in late Triassic time ('Indonesian'). He thinks that the stratigraphic evidence indicates only one orogenic cycle (Wilson cycle) stretching from the late Proterozoic to the late Triassic. Zone 1 of Mattauer *et al.* is viewed by Hsü as an Austroalpine-type rigid basement nappe, whose main internal deformation had already occurred probably in late Proterozoic time. In zone 2, Hsü sees Pennine-type folded nappes of basement material, whereas in the 'Central Qin-Ling Dome' (zone 3) an equivalent to the *schistes lustrés* and ophiolites is seen. Hsü, like Mattauer *et al.*, interprets this as the remnants of a former ocean. He believes the so-called 'Devonian trough' (zone 4) was a region of turbidite sedimentation, but disputes the Devonian age assigned to the turbidites here, for that age comes from macrofossils in exotic limestone blocks found in the turbidites. Hsü points out that Triassic ammonites have been recovered from similar rocks in the same zone farther west, thus making at least some parts of the turbidite sequence of the 'Devonian trough' Triassic.

The Triassic to early Cretaceous age of the main linear granite belt north of the Qin-Ling Shan, the 'Variscan' age of the earliest known subduction-related magmatism ('Variscan' or 'Hercynian' in Asia may in places reach well into the Triassic, emphasizing once more the misleading consequences of the employment of these terms outside their European type areas), and the pronounced difference both in the palaeophytogeographical and in the palaeomagnetic²⁰ signature of the Permo-Carboniferous rocks on both sides of the Qin-Ling Shan, all seem to converge to support a Triassic collision. This becomes

- Main Precambrian continents

Tectonic map of Asia showing the Phanerozoic sutures; Tethyside sutures, of which the Qin-Ling Shan (boxed area) is a part, are emphasized. The map also shows the distribution of late Palaeozoic (Permo-Carboniferous) glaciogenic sediment and flora distribution (except the Angara flora) to identify independent blocks of that age and their possible palaeobiogeographic affiliations. Notice how sharply the Qin-Ling suture separates the North Cathaysia realm from the South Cathaysia realm. Also notice the pronounced Triassic to Cretaceous batholith belt immediately north of the Qin-Ling suture.

Numbers refer to sutures: (1) Mindoro; (2) Taiwan; (3) Poso; (4) Butung; (5) Peleng; (6) New Guinea/Papua; (7) Sabah; (8) Sibiu; (9) Burma; (10) Indus-Yarlung Zangbo; (11) Shiok; (12) South Ladakh; (13) Waziristan; (14) Makran; (15) Sumatran; (16) Meratus; (17) Shiika; (18) Sittang Valley-Myitkyina; (19) Banggong Co-Nu Jiang; (20) Rushan-Pshart; (21) Waşer (Farah-Rud); (22) Da Hinggan Ling; (23) Huang Shan; (24) Central South China; (25) Longmen Shan; (26) Litang; (27) Jinsha Jiang; (28) Inner Mongolian; (29) West Ordos; (30) Qin-Ling; (31) Anyemaqen Shan; (32) Hoh Xil Shan; (33) Natuna; (34) Suture of the southern synclinorium of the western Kuen-Lun; (35) Herat; (36) West Thailand (Nan-Uttaradit); (37) Song Da; (38) Medial Malaya (Bentong-Raub); (39) Lancan Jiang; (40) Petchabun; (41) Suture of the northern synclinorium of the western Kuen-Lun; (42) Qilian Shan; (43) Qimantag; (44) Song Ma. Lettering: (B) Borneo accretionary complex; (EMB) East Malaya Block; (M) Makran accretionary complex; (NCB) North China Block; (NTB) North Tibetan Block; (S) Songpan-Ganzi accretionary complex; (SB) Sichuan Block; (SECB) Southeast China Block (SB+SECB=South China Block); (Z) Li Chunyu *et al.*'s North China suture (ref. 14). The map is compiled from data in refs 4 and 19.

the more plausible when one follows the suture both westwards into the Kuen Lun and eastwards into Korea, where it continues into the orogens of Triassic age^{4,14,16}.

A very significant point made by Mattauer *et al.*⁷ and Peltzer *et al.*⁸ is the presence of significant strike-slip motion along the Qin-Ling Shan in both Tertiary-Quaternary time and probably also earlier. The post-Eocene movement, of the order of several hundred kilometres, is rightly ascribed to the effects of the Himalayan collision. But the possibility of a few thousands of kilometres of motion during the Mesozoic (see ref. 20) presents acute problems in attempting palaeogeographic and palaeotectonic reconstructions. Thus, the isotopic or palaeontological ages obtained from slivers, or even entire terranes, dragged along such giant strike-slip systems may have no relevance to the orogenic history of the edifice in which they now lie embedded.

The two papers by Mattauer *et al.* and Peltzer *et al.* clearly indicate, in the light of the above discussion, that the Qin-Ling Shan has had an extremely complicated, multi-stage evolution, during which its constituent elements may have been repeatedly redistributed by several episodes of important strike-slip motion along the belt. This alone may help us to see why the interpretation of the tectonic history of this orogen is so difficult and prone to controversy. This must be true, albeit in different degrees and in different combinations, along all of the suture zones that hold together the Asian edifice, showing²² how dangerous and misleading it must be to consider orogenic evolution along cross sections alone. Much more work remains to be done before even a glimpse is obtained of the problems that are involved in understanding the orogenic evolution of the Qin-Ling Shan, as well as the assembly and disruption of Asia. □

Cosmology

Radio supernovae as probes for Hubble's constant

from Alan P. Marscher

IT SEEMS remarkable that, over half a century after Edwin Hubble discovered that all distant galaxies are receding from us with velocities proportional to their distances, astronomers still cannot agree on the value of Hubble's constant, the slope of this relationship. This important parameter corresponds to the expansion rate of the Universe in most cosmological models, and can be used to determine the present age of the Universe in the standard big bang model. On page 25 of this issue, a new method, which utilizes the observed expansion rate of radio-bright supernovae to estimate Hubble's constant, is reported by Bartel and his colleagues¹. The method, while somewhat dependent on a model, obviates the systematic uncertainties inherent in optical distance determinations.

Using optical distance indicators, Sandage and Tammann² arrived at a value $H_0 \approx 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$ for Hubble's constant, with an estimated upper limit of about 60. On the other hand, de Vaucouleurs³ and Bothun and colleagues⁴ obtained values between 90 and 100, with a lower limit of about 85. That these two limits are so incompatible illustrates the importance of systematic errors in the derivation of H_0 (see ref. 2 for an excellent summary). Nearly all critical distance determinations depend on the use of very few distance indicators (such as Cepheid variables) to obtain the distances to more remote galaxies. Therefore, uncertainties in the use of this small number of primary distance indicators become systematic errors in the determination of H_0 . What is clearly needed is a method independent of the derived distances of local group galaxies.

Fritz Zwicky maintained that supernovae were the only worthwhile extragalactic distance indicators. Whether or not this proves to be the case, supernovae

at least have the advantage that their luminosities are high enough to allow detection at distances greater than 1,000 Mpc. It is also well established that they represent exploding stars with expansion velocities that can be measured via the Doppler shifts of the emission and absorption lines in the optical spectrum. One method for calculating the distance to a supernova, attributed to W. Baade and A. Weselink, uses the observed expansion velocity and the assumption that the optical-infrared continuum represents black-body emission from an opaque, expanding sphere of gas. The shape of the continuum yields the temperature of the black body which, together with the radius calculated by multiplying the expansion velocity by the time since the onset of the explosion, allows one to calculate the luminosity. The relationship between this derived luminosity and the observed flux depends only on distance, which can then be determined. The main difficulty with this method is that the optical-infrared continuum does not fit a black-body curve precisely and the deviations must be modelled theoretically for the method to be applied successfully⁵.

Bartel *et al.*¹ use what at first glance appears to be a much more straightforward approach: by using centimetric-wavelength, very-long baseline interferometry (VLBI), they have been able to measure the angular diameter of the radio source associated with supernova 1979c in the galaxy M100 in the Virgo cluster. Since the true diameter of the supernova can be derived from the optically-determined expansion velocity, the distance to the supernova (and the galaxy containing it) can be readily calculated. Using this distance to M100, they derive a value of $H_0 = 65^{+35}_{-25} \text{ km s}^{-1} \text{ Mpc}^{-1}$. While this range of possible values hardly solves

the controversy over Hubble's constant, it is exciting that an attempt has been made to employ such an apparently straightforward technique.

The large uncertainty in the value of H_0 obtained by this method arises mainly from two distinct difficulties. The first is observational. Extragalactic supernovae are faint at radio wavelengths, so much so that only a handful have been detected by the most sensitive radio instruments available. The successful use of VLBI requires a strong detection by at least 3 or 4 antennas, but with the current VLBI configuration supernova 1979c is only weakly detected. The combination of the very-long baseline array (to be built in the United States by about 1990) and large European radio dishes should improve this situation substantially.

The theoretical difficulty is a little stickier. The optical expansion velocity is only relevant here if the radio emission is co-spatial with the optical spectral-line emission. In fact, the leading model⁶ for the radio light curves of supernovae places the radio emission in a shock wave outside the bulk of the debris from the explosion. Bartel *et al.*¹ assume that the radio brightness distribution lies somewhere between that of a uniform sphere and that of a ring with an expansion velocity closely related to that obtained from the optical spectra. It has been shown⁷ that these extreme cases lead to values of H_0 which bracket those obtained using more realistic brightness distributions. This uncertainty in the appropriate geometry leads to the wide range of values for H_0 allowed by the data of Bartel *et al.* Eventually, the actual radio-brightness distribution of a supernova might be measured directly using VLBI, obviating the need to rely on theory. Even then, frequency-dependent apparent diameters (possibly observed by Bartel *et al.*), and other complications, might limit the ultimate accuracy of the method.

If, as expected, further refinements and continued observation improve the accuracy of the new technique, we will be blessed with a cosmological probe that is independent of all the systematic uncertainties that haunt the current optical methods. Such a breakthrough would enable cosmologists to get on with their business of model making, released from the nagging fear that the size scale and age of the Universe they have adopted could be off by a factor of two. □

100 years ago

HYDROPHOBIA

ONCE more M. Pasteur is attracting the attention of the civilised world by his brilliant investigations . . . a boy of nine years old had been terribly worried on the 4th of last July; not only bitten in parts covered by his clothes but also on the hands. He was rescued covered with foam, and bleeding from no less than fourteen wounds. There was no question that the dog was mad, and in all human probability this child, Joseph Meister, was doomed to a certain and horrible death. M. Pasteur felt himself justified in applying the means to this suffering fellow creature, which had already proved efficacious in the case of brutes.

The inoculations were made with a subcutaneous needle, began on the 7th, and were

concluded on the 16th of July. "Control experiments" were made with the same injections upon rabbits, and proved that the virus was active. Moreover, since the effects of the modified virus, when introduced into an unprotected animal, are rapid and severe, and its period of incubation extremely short, the result of the attempt to rescue the child from a horrible death would soon be apparent. If he had died of hydrophobia, it would probably have been within a month. If he survived this period there was every reason to hope that he would be as much protected against its future manifestation as the dogs which had been tested before.

Joseph Meister was in perfect health at the end of August, at the end of September, and at the end of October. M. Pasteur believes that he is safe from hydrophobia for the rest of his life. From *Nature* **33** 1, 5 November 1885.

A new protein sequence data bank

SIR—A protein sequence data bank, called PGtrans, is available from our laboratory. This data bank is generated by automatic computer translation of the well-known nucleotide sequence library GenBank (established by Bolt, Beranek and Newman Inc. and Los Alamos National Laboratory). For this we designed a translator program which scans and interprets the specific information fields of each GenBank entry: DEFINITION, SOURCE and FEATURE table. The translator program can thus decide if the corresponding nucleotide sequence includes a coding region, and what is the proper genetic code to use to translate it into a putative protein sequence.

For each coding region successfully translated, the program creates a PGtrans entry including a text constituted of several fields: CODE, NAME, SOURCE, REFERENCE and COMMENT, followed by the amino-acid sequence. The translator program checks for unexpected 'stop' codons eventually found in coding regions. If a 'frame shift' allows the errored coding region to be rescued, the tentative amino-acid sequence is included in PGtrans. However, a warning is included into the COMMENT field to indicate a potential problem. The current PGtrans databank corresponding to GenBank (35.0) contains 3,107 entries for a total of 483,649 residues. Figure 1 shows the

entry-length distribution for PGtrans 29.0. A listing of the encounter anomalies is routinely communicated to the makers of GenBank.

The main purpose of PGtrans is to offer a direct access to all amino-acid sequences coded among GenBank nucleotide sequences and thus to be an efficient tool for protein homology searches. Its format is compatible with the rest of our sequence analysis software¹ and will be consistent with the recommendations of the CODATA task group on protein sequence data banks². Since we conserved the minimum of text information necessary to identify the protein, PGtrans is a compact data bank (1.4 Mbytes) which could fit for few more years into microcomputer environments. Among other efforts in gathering protein sequence data³⁻⁵, the role of PGtrans is to provide a rapid update of new protein sequences determined by nucleic acid analysis. Magnetic tape copies (card image) of PGtrans will be distributed free of charge upon request to our laboratory.

Three-dimensional electron lattice

SIR—*Nature* reported on 14 February (313, 527; 1985) the discovery of a three-dimensional electron lattice in *n*-HgCdTe by Rosenbaum *et al.* (*Phys. Rev. Lett.* **54**, 241; 1985). In fact the discovery was made in my laboratory in 1979. Our response to Rosenbaum *et al.* and relevant references can be found in *Physical Review Letters* for 22 July (55, 443; 1985).

Shadow boxing with Darwin

SIR—Dawkins's taunting review¹ of Eldredge's book *Time Frames: The rethinking of Darwinian evolution and the theory of punctuated equilibria* raised important issues of evolutionary theory that can only but invite comment.

There always have been two components to Eldredge and Gould's theory of punctuated equilibria, as the phrase suggests explicitly — 'long periods of stasis (equilibria) punctuated by relatively much shorter periods of change. To reiterate, yet again, that the periods of change potentially fall within traditional boundaries of gradual Darwinian evolution by means of natural selection, and to ignore the major periods of stasis (a device which allows Dawkins to dismiss the whole concept as an "interesting little theory . . . lying firmly within the neo-Darwinian synthesis") reduces scientific evaluation to a parlour game of one's own invention, which whilst entertaining and superficially coherent, does not offer proper scientific guidance for the general reader.

If we accept, for the moment, that stasis is a widespread observation in the geological record, and if too we accept that the forces behind selection are the only means for promoting biologically useful novelties throughout a population (setting aside contemporary knowledge that the molecular behaviour of the genes can effect similar changes), then it is surprising that little significant evolution occurs over periods of time that may span from hundreds of thousands to millions of generations, in a diverse range of species. The point is not that evolution is gradual "during the times that it is actually happening" (Dawkins' emphasis) but that it seemingly is not happening for most of the time. This was the message of the infamous Chicago meeting, which many of us took home, and which demands an explanation.

Attempts to bring stasis within the neo-Darwinian synthesis (see ref. 2 for the best of them) are not wholly satisfactory in that they plead for a general process called stabilizing selection, coupled to an

assumed inertia of developmental systems, applicable to all examples of stasis irrespective of species or conditions. This says that no evolutionarily significant shift in the average phenotype of a population took place because the ecological and developmental conditions were such that mutationally deviant individuals were continually selected against. This explanation, whilst theoretically self-evident, presupposes a uniformity of environment over vast distances of time and space that surely must be unacceptable to ecologists familiar with the ever-changing web of relationships that go into the making of ecological niches. It is difficult to accept that the heterogeneity of niches, once set up, is so stable and no longer subject to further subdivision that the usual ecological pressures, forcing variant individuals to selectively adapt to progressively specialized niches, no longer exist. Furthermore, developmental inertia is becoming the panacea for all our unsolved problems. When we don't want any appreciative directional selection to be taking place we appeal to the severity of genetic and epigenetic constraints implicated in the development of a single-celled zygote to a multicellular adult. When we do need to explain, nevertheless, that evolution is seen to be taking place sometimes, such constraints miraculously disappear.

There are other potential explanations, Darwinian and non-Darwinian, for stasis and its occasional interruption, which have not been fully explored, as yet^{3,4}. However, notwithstanding all such attempts, our general ignorance of developmental genetics and our even greater ignorance of the ecological flux and microheterogeneity of past environments, simply make it premature to wage polemical wars and to demote contemporary observations and their interpretation as "a technical parochial affair if ever there was one". The writings of Darwin, and indeed those that contributed to the formulation of the neo-Darwinian synthesis in the 1930s, are not Old Testament tracts to be poured over by armchair exegesis. They cannot supply, without resorting to too many *ad hoc* assumptions, all the answers to the multiple causes of the ebb and flow of evolution. This is relevant not only to the tempo of change observed in the geological record, but also to the evolutionary consequences of the unexpected molecular dynamics of the genes themselves. Physics moved on from Newton, and biology might need to move on from Darwin, if we are to explain, satisfactorily, all that we observe.

Dawkins is defending a tradition which hardly needs defending (for contemporary theories whilst non-Darwinian are not anti-Darwinian, despite the journalistic, and occasional professional, recourse to hype), when at the same time he is getting a little of his own back on the justifiable attacks on his own interesting little misjudgement of the "gene as the unit of

selection" (selfish gene). Ironically, this technical blunder, (despite Dawkins' protestation that it "has enriched the synthetic theory"), stood Darwin on his head and sent many a true Darwinian rushing to set the old gent firmly on his feet. Dawkins' style seems to be a self-conscious attempt to emulate the rapier-like thrusts of Sir Peter Medawar in his prime, who demolished bogus scientists with unremitting glee. Unlike Sir Peter, however, we are left with the image of a man who, in largely ignoring the real scientific issue under review, is shadow boxing with himself: a stance not much help for an informed evaluation of evolutionary processes.

The length of myosin subfragment-one

SIR—A recent *News and Views* comment¹ on electron microscopy² of crystals of isolated myosin heads (S1) emphasized that these results yielded a length supporting earlier rotary shadowed views of intact myosin and S1 molecules. Results obtained from X-ray scattering³ and (by implication) certain electron microscopic acto-S1 reconstructions which yielded shorter structures were rejected as incorrect. We contend that because of a confusion arising from comparing two different kinds of lengths, there is little or no evidence for either support or rejection.

Winkelmann *et al.*² report at least 160 Å for the 'length' of S1. Measurements from their projected images (corrected for depth) indicate that this is a *contour length* and that the *maximum chord* (l_{\max}) observable within their structure is 120–140 Å long. The lower limit arises from the contour drawn in Fig. 11a of ref. 2. The upper limit derives from the assumption that there are crystal contacts along the long direction of the molecule. While we agree that the contour in Fig. 11a probably underestimates the volume, the data do not necessarily lead to the conclusion that the missing mass is along the long direction of S1; the molecule could just as well pack in the crystal without contacts along this direction.

X-ray scattering results give an l_{\max} = 120 ± 10 Å and acto-S1 reconstructions give l_{\max} = 115–150 Å (see Table 1 of ref. 4) which are consistent with the crystal values. (The largest value in this range arises from scallop S1 with regulatory light chain.) Although these results, as well as the crystal results, could underestimate the true length of the myosin head (for different reasons), the current S1 crystal results do not require that the l_{\max} (190 Å) of the entire myosin head^{5,6} or S1⁷ esti-

mated from rotary shadowing projections be correct. It is nevertheless encouraging that there are features of S1 on which nearly all results concur: a curved shape with most of the mass located near one end.

Control of the cell cycle in yeast

SIR—In a recent *News and Views* article on yeast cell biology (*Nature* **316**, 678), I. Herskowitz states that mutations in yeast that result in G_1 arrest with reduced protein synthesis are relatively unlikely to reflect specific cell-cycle controls, in contrast with mutations such as *cdc28*, which induce G_1 arrest without reduced protein synthesis. There are several reasons for viewing this statement with caution.

First, successfully meeting the criteria of continued protein synthesis for G_1 arrest mutants does not exclude the possibility that the mutation may effect some continuous aspect of metabolism unrelated to growth control *per se*. For example, a mutation in the gene encoding ribonucleotide reductase could in principle mimic the effect of exogenously applied hydroxyurea, which can lead to G_1 arrest with continued protein synthesis.

Second, there is a wide body of evidence which suggests that attainment of a critical amount of protein is necessary for traversal of the G_1 period, and it seems relatively safe to assume that cell cycle control points operate both before and after such an event. There is no *a priori* reason that physiologically important cell cycle controls are more likely to operate after this event; in mammalian cells, G_1 arrest induced by depletion of polypeptide growth factors is usually accompanied by a marked fall in protein synthesis.

Finally, two of the mutations in *S. cerevisiae* that lead to G_1 arrest with reduction of protein synthesis, *cdc25* and *cdc35*, are now thought to be specific signal transduction components of the cAMP pathway. These gene products might exert their growth-regulatory effect by influencing protein synthesis, or a feedback mechanism might slow protein synthesis in response to inactivation of these gene products. In any case, any comprehensive view of cell cycle control should not exclude such regulatory proteins from consideration.

There are at least three good reasons
for you to publish in the

COMPTES RENDUS DE L'ACADÉMIE DES SCIENCES

The time required for publication is exceptionally short

- The reviewing system, very much reinforced over the past few years, is kept under close control so as to avoid unnecessary delays
- What is more, thanks to the latest techniques, the notes, once accepted, are printed within 5 weeks at the most

Another great asset, since 1984, is the introduction of the English language

This leading scientific journal, covering all fields of science, guarantees a
distribution

Editorial Policy

The Comptes-rendus de l'Académie des sciences consists of three different series

Series 1 - Mathematics

Series 2 - Mechanics, Physics, Chemistry, Earth Sciences, Space Sciences

Series 3 - Life Sciences

A note must be the first publication of an important discovery or a significant new result.

It should be short: 4 printed pages, abstracts

and summary included.

As an indication, this corresponds to 11 typed pages of 25 lines, each containing 55 characters or symbols.

Every English-language note must include a one page summary in French. If required, the Academy will provide the translation.

No page charges are levied. 25 reprints free of charge are provided.

NEW

BIOLOGY OF THE CELL

BIOLOGIE CELLULAIRE

NEW

Published under the auspices of the European Cell Biology Organization

Editor-in-chief

D. SANDOZ, *Centre de Biologie Cellulaire du CNRS,*
67 rue Maurice Günsbourg, 94200 Ivry Sur Seine

Editors: **B. ANDRIEUX**, *Ivry*;
R. BOURDU, *Orsay*, **R. CHARRET**,
Orsay, **M. DUBOS**, *Clamart*;
M. PHILIPPE, *Villejuif*, **D. SZAFARZ**,
Orsay.

Aims and Scope

The journal **BIOLOGY OF THE CELL** publishes results of original work concerning the structure and the function of cells, organelles and macromolecules. Areas of interest include all aspects of cellular and molecular biology in the context of developmental biology, genetics, immunology, physiology, virology. Especially welcome are results obtained by complementary methodologies which permit the comprehension of structural/functional relations in normal and pathologic cells.

The journal publishes original articles, letters to the editor, rapid communications (short articles of special interest) and review articles covering rapidly evolving topics of cell and molecular biology.

The politics of pesticides

Eric Ashby

Pesticides and Nature Conservation: The British Experience 1950 – 1975.

By John Sheail.

Oxford University Press: 1985. Pp.276. £19.50, \$29.95.

THE various messages conveyed by this book are important. But just as important are the seven pages at the end which carry the sources from which it was written — nearly 300 references, practically all of them from the files of the Nature Conservancy, a body set up under royal charter as the fourth of Britain's research councils in 1949 (added to the Department of Scientific and Industrial Research, the Medical Research Council and the Agricultural Research Council).

What is unusual about that? It is that the files were opened to John Sheail, even though most of them were less than 30 years old (in Britain, a ban prevents access to the papers of official government organizations for that period). How this miracle of diplomacy was achieved in a country that has no Freedom of Information Act, and which is paranoid about the disclosure of information less than 30 years old, the author does not explain. But the benefits of this relaxation are clear. The recent history of pesticide control is now public knowledge; in part, at any rate, for of course the files of the relevant Ministries may remain closed until the year 2015 (for matters being discussed today) and the files of the industries that produced pesticides are never likely to see the light.

The value of having this sort of information made public is that people concerned to influence environmental policy can find guidance on how to do it and (from many episodes described in this book) how *not* to do it. Nothing but good can come from disclosure of the complexities and legitimate conflicts which have to be resolved before decisions about the environment can be made (though only a reckless optimist would hope that the Department of the Environment might be shamed into releasing some of its papers to historians). In this sense the book is a landmark and those who had the courage to authorize the files to be opened are to be congratulated.

Skimmed over, the book itself is a sober, detailed account of the use and control of insecticides and herbicides in Britain, as seen by the Nature Conservancy and with emphasis upon the part played by the Conservancy in solving the scientific problems and interpreting the solutions for politicians. In rough outline it is a familiar story, for "every schoolboy knows" the gist of the message in Rachel Carson's *Silent Spring*. But to put the book aside with the conclusion that it is no more than a parochial account of Britain's

experience in pesticide control would be a misjudgement. True, it is a case-study of environmental decisions for one narrow issue in one small country. But it is out of such case-studies that general principles emerge, and the intricate details demand close reading: the distinction between correlation and causation in field observations; the subordinate part scientific evidence plays in some political decisions; the resolution of conflicting self-interests when there is "right" on both sides.

The story Sheail has to tell is best illustrated by the several themes which characterize his case-study. One of them is the difficulty of linking cause and effect in ecology. Forty years ago the *Atlantic Monthly* published an article by V.B. Wigglesworth, a British entomologist, about the possible side effects of DDT; it might, thought Wigglesworth, kill the predators of the very pests we want to destroy, when the predators might, in the long term, be more effective agents of control. It was only concern that DDT might be a hazard to human health — not to other organisms — that prompted official enquiry into its effects, and not until the 1950s that Wigglesworth's warning took root. By that time, however, it was clear that millions of pounds worth of crops were being saved in England and Wales by the application of insecticides, and large profits were being made by the manufacturers of sprays and equipment. There would have to be compelling reasons for any government to restrict this practice.

It was left to the Conservancy and to voluntary bodies such as the Royal Society for the Protection of Birds to find those reasons. There was an increase in the numbers of dead birds and mammals found after spraying; but it was easy to explain this away by saying that the public-

ity given to bird-deaths stimulated volunteers to look for dead birds, and the cause of the increase in numbers of dead birds was simply the increase in the numbers of people looking for them. Challenged to produce credible evidence that the birds and mammals had been killed by pesticides the Conservancy was obliged to set up its own research unit, with pitifully inadequate funds, to tackle problems which were insoluble without more refined techniques in analytical chemistry than were available at the time. It was not until the early 1960s that the Conservancy's research unit was able to publish analyses for pesticide residues in the bodies of dead birds, showing that these residues were higher among raptorial and fish-feeding birds, whose diet was contaminated by lower concentrations of the residues; it confirmed the hypothesis of concentration of residues in the food-cycle. The peregrine falcon was the protagonist in this drama. Its principal prey was live birds; these (with the irony of Greek drama) were the falcon's undoing. By 1962 its pre-war population was halved. But by then the government had accepted the scientific evidence. Persistent organochlorine pesticides were restricted, and the peregrine falcon population is well on the way to recovery.

A second theme of the book is the contribution voluntary bodies have made to the control of pesticides. It was a joint committee of the British Trust for Ornithology and the Royal Society for the Protection of Birds that hired chemists to do post-mortems on birds thought to be killed by organochlorines or mercury on seed dressings. The committee was able to show a clear correlation between sowing programmes and mortality in many parts of England. The record of voluntary conservation bodies in Britain is in every way as impressive as the efforts of the Sierra Club and the Audubon Society in America, but with this difference: in Britain the voluntary bodies have worked by bringing informal pressure to bear on the government and the public, while in the United States the voluntary bodies have frequently had to resort to law. In the United States the battle against organochlorine

Crop spraying with pesticide — the story is not over yet.

pesticides, for example, was won through the Environmental Defense Fund.

A third theme also is concerned with voluntary effort, and it is peculiarly British. The control of pesticides comes under a so-called Pesticides Safety Precautions Scheme which has persuaded the manufacturers voluntarily to abandon some pesticides altogether. From time to time governments are pressed to impose mandatory control (and there is still a need for it in some non-agricultural uses of pesticides), but every time the matter is looked into, the advice given (even by the Royal Commission on Environmental Pollution in its Fourth Report in 1974) is that there is no case for replacing the voluntary system.

Finally, Sheail's book has some vivid illustrations of the familiar pattern of events in environmental politics, a pattern which anyone who wants to take part in such activities has to understand. There is a prologue of silent scientific work to which politicians, even if they know about it, are indifferent. There follows a sensa-

tional episode, such as the *Torrey Canyon* disaster, or an emotive popularization of some hazard, such as was so successfully done in *Silent Spring*. (It was the chairman of a Congressional subcommittee on agriculture who described the public opinion left by *Silent Spring* as "the worst residue problem we have to face today".) The cautious scientists, striving to solve the problems, are often bitterly criticized during this emotive phase. Then come pressures for legislation or, in the United States, lawsuits; and finally there has to be a compromise between those who want to exploit the environment for profit (either by growing crops or making pesticides) and those who want to protect it.

Above all, John Sheail's book is a record of missionary work by scientists among civil servants and politicians. There is no climax, but nor should there be: the story is not over yet. □

Lord Ashby is a Fellow of Clare College, Cambridge CB2 1TL, UK. He was Chairman of the Royal Commission on Environmental Pollution from 1970 to 1973.

Viewed from above

Melbourne G. Briscoe

Introduction to Satellite Oceanography. By G.A. Maul. *Martinus Nijhoff*: 1985. Pp.606. Dfl.220, \$80.

Satellite Oceanography: An Introduction for Oceanographers and Remote-sensing Scientists. By I.S. Robinson. *Ellis Horwood*: 1985. Pp.455. £42.50, \$63.75.

Methods of Satellite Oceanography. By Robert H. Stewart. *University of California Press*: 1985. Pp.368. \$38.50, £32.75.

IT WAS not so long ago that the proper background for a physical oceanographer was deemed to lie more in one's heritage and sea legs than in any particular formal education. Experience and practical apprenticeship were far more important than classes and books. In recent years it has been seen to be necessary to complement that approach of thoughtful explanation and observation with a good dose of common sense about electronic and mechanical instruments, and a solid grounding in mathematics and physics. Such mandatory education now includes the need for more than a passing knowledge of numerical methods, thermodynamics, synoptic and boundary-layer meteorology, and, depending on the chosen specialization, chemistry, geology and biology.

In this rapid evolution and expansion of formal training, however, it has been easy to forget that oceanography — even today's physical oceanography of potential vorticity balances and dispersion relations — is still mainly an observational science. Our ideas about how the ocean works are driven by what we see of its workings.

These three books bring this issue back into the limelight. They all attempt to display and explain the enormous potential of remote sensing of the oceans, principally from satellites, and to provide the information one might need to use and to understand this newly available tool. Maul aims his book at "a wide range of oceanographers, managers, and engineers" (is this a hierarchy, I wonder, and, if so, which way does it go?); Stewart says his is for "scientists with varied backgrounds"; and Robinson addresses his more eclectic book to an equally broad audience: "practising oceanographers . . . sensor technologists and remote-sensing specialists . . . and students of both oceanography and remote sensing".

The content and success of each of the books reflect the authors' backgrounds. Maul and Robinson both specialize in the infrared and optical properties (such as colour) of the sea surface, while Stewart concentrates on radio and radar scattering from the surface. Robinson's book provides some useful material on orbits and data handling, much of which is probably ephemeral, whereas Stewart has tried to include fundamental and perhaps more durable material about the basic physics of the sensors and the associated electromagnetic emission and scattering processes. Stewart's book is the most pleasing typographically, and includes a number of impressive colour plates which illustrate certain applications. Maul contains considerable detail and comes the closest to being self-contained on a number of topics. Robinson gives a lot of help to the person actually working with the data (not one of his intended audience, by the way), but a large number of typographical errors lessens one's confidence in some of his material.

In books such as these, it is unlikely that the reader will start at the beginning and read to the end; a comprehensive and detailed index is therefore essential. As a test, I tried to look up the established accuracy of sea surface temperatures as measured from a satellite, which is one of the oldest and most useful products of remote sensing. Only Robinson allows direct access to the topic via the index (but under the heading "SST"). Stewart does not even have an entry under "Temperature", although his discussion of the topic is arguably the best of the three. (Apparently, if one works very hard, it is possible to get about 1K accuracy.)

The authors are all successful in their goal of making remote sensing more accessible to the oceanographer, perhaps more so as textbooks — they are all based on course notes — than as reference books. Robinson, however, mostly fails in his attempt to provide an oceanographic background for the remote sensor; an entire book would be necessary for this task, and would be very difficult to write, but such a volume is clearly needed to stem the trend of space engineers publishing second-rate oceanography in non-oceanographic journals and in non-refereed conference proceedings.

But I wonder if these books are really necessary. Even if they meet their stated goals, was the goal worth addressing? Traditionally, a new tool becomes known to the science community by its being used and by publication of the results in science journals. These authors argue, however, that here the tool (sensors on satellites) is so different, so complicated and so inaccessible in terms of its construction and its data handling, that the issue must be forced, rather than just being allowed to happen. I suppose they are right, but you cannot force good science and it is good science based on remote sensing that will ultimately sell the new tool.

There is considerable promise in satellite oceanography as a broad but not detailed observational tool; this is precisely the missing dimension in traditional oceanographic measurements, so with perseverance by all and tolerance by the traditionalists this new view may yet pay off. These books are a step in the right direction. □

Picking the winners by number

David E.H. Jones

The Awards of Science and Other Essays. By Eugene Garfield. ISI Press, Philadelphia/STM Distribution, Enterprise House, Ashford Road, Ashford, Middlesex TW15 1XB, UK: 1985. Pp.572. \$30, £26.

CURRENT CONTENTS, which every week reproduces the title pages of a selection of learned journals, must be the tersest and most functional magazine in existence. Almost its only concession to literature (as opposed to *the literature*) is the section "Current Comments", in which the editor, Eugene Garfield, looks up from his photocopier and discourses on whatever topic has taken his fancy that week. He has been publishing collections of his "Comments" since 1973, under the general title *Essays of an Information Scientist*; this book is the seventh in the series.

Of the 61 essays here reprinted, nine deal with recent research on biomedical topics such as cystitis and gerontology, and ten are tributes to notable information scientists or recent Nobel Prize winners. There is also a description of an artwork (with colour plate), a discussion of science books for children, and two articles by other authors which Garfield comments upon. But most of the essays deal with aspects of information science: in particular the services provided by the Institute for Scientific Information, founded by Garfield in 1960, and analyses of its compilations of scientific citations which are published as *The Science Citation Index*.

Most researchers, I imagine, use the *Index* regularly, if only to look themselves up and find out how they are doing: how often their most recent papers have been cited, and by whom. Computer technology not only enables the enormous lists of citations to be compiled and indexed, but also allows Garfield to indulge in his favourite hobby of scanning the lists for highly cited papers. Thus the book includes accounts of the hundred most cited papers ever; a hundred "citation-classics" from *The Lancet*, and another hundred from *The New England Journal of Medicine*; several compilations of the articles most cited between 1961 and 1982; and several essays on the citation-patterns of different scientific disciplines.

Each such essay contains a wealth of statistical material on papers and their citation-rates, the ranking of journals by citation-frequency in the rest of the literature, the number of citings of "classic" (highly-cited) papers as a function of time and so on. Garfield uses this material as a springboard for discussing developments in the field involved, and its current "hot

topics", usually buttressed by explanations from the principal authors concerned. Intriguing "maps" of the scientific frontiers are sometimes included, based on the flow of citations between the various authorities.

All this is splendid stuff, and gives a lot of information about the most active (or at least the most verbal) areas of science. However, Garfield's preoccupation with picking winners tends to give a one-sided impression of what science is all about. Thus the title essay "The Awards of Science" deals with just that; the scientific prizes and awards available to scientists, and how many of the recent prize-winners have been spotted among ISI's "most-cited authors". The object of the essay is to dispel the impression that the Nobel Prize is the only possible goal for a scientist — there are many other prestigious

prizes to compete for. "To set a practical limit for the essay, we have only included those awards that bestow an honorarium of at least \$15,000."

This image of science as a sort of competitive hit-parade is probably an occupational bias of the computerized citation-analyst. Fortunately Garfield's interest in science transcends this limited view. His concise accounts of research in many fields, and of the achievements of many scientists, are well worth browsing through for their erudition and informativeness — and, as one would expect, they are impeccably, not to say obsessively, documented and referenced.

David E.H. Jones is a guest staff member in the Department of Physical Chemistry, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, and a science consultant to industry and the media.

The moving spirit

Simon D.M. White

Gravitational Physics of Stellar and Galactic Systems. By William C. Saslaw. Cambridge University Press: 1985. Pp.491. £50, \$90.

As William C. Saslaw points out in his new book, gravitation is the spirit which underlies almost all astronomical phenomena. Rightly, then, the study of gravitational dynamics has had a major part in astronomy since the time of Newton, and today it is the foundation on which we build our understanding of the structure, formation and evolution of planetary systems, of star clusters, of galaxies, and of the large-scale distribution of galaxies. Recent research has been greatly stimulated by the advent of computers that are able to integrate the equations of motion directly for systems containing thousands of particles. As a result gravitational dynamics has become, in some part at least, an experimental science.

In view of its importance in modern astronomy, it is surprising that there is no recent all-embracing account of the subject. *Gravitational Physics of Stellar and Galactic Systems* thus addresses itself to a well-recognized gap in the literature. As the title suggests, Saslaw is here more interested in elucidating physical processes than in modelling astronomical systems. His book is written in an easy-going conversational style, and is laid out as a survey of the phenomena which govern the gravitational evolution of many-body systems.

The whole field is divided into four general areas: homogeneous systems, infinite inhomogeneous systems, finite spherical systems and finite flattened systems. The first part discusses descriptive formalisms such as the Liouville, Boltzmann, Fokker-Planck and BBGKY hierarchy

equations, together with fundamental processes such as collisional relaxation, dynamical friction, collective scattering and Landau damping. The second part concentrates on clustering in an infinite universe, with particular emphasis on thermodynamic considerations, while the third deals with the structure of spherical systems and their evolution under the influence of collisional relaxation and binary formation. The last part discusses some aspects of disk galaxy dynamics and a few other assorted topics. The sophistication of treatment and completeness of coverage decrease steadily from one part to the next, even though the relevance of the subject matter to contemporary research increases. The book restricts itself to processes involving purely Newtonian gravity.

On the dust jacket, the book is described as suitable as a text for graduate students. However the depth and completeness of coverage are too patchy and too idiosyncratic to serve students well. Thus there are long and involved calculations of collective scattering and of the growth of clustering from an initially unclustered state; these are difficult to follow and lead neither to astronomically useful results nor to a significant sharpening of physical intuition. On the other hand, the treatment of the structure and instabilities of ellipsoidal and disk-like systems is at best sketchy.

Overall, the selection of material reflects the author's own research interests, and the distribution of emphasis differs somewhat from that typical of modern research in the field. The book's length is a consequence of its enjoyable but discursive style, rather than a reflection of the completeness of its contents. Unfortunately, we shall have to go on waiting for a comprehensive discussion of modern gravitational dynamics.

Author and augur in theoretical physics

John Stachel

Wolfgang Pauli: Scientific Correspondence with Bohr, Einstein, Heisenberg a.o. Vol. II: 1930–1939. Edited by Karl von Meyenn. Springer-Verlag: 1985. Pp. 783. DM 298, \$112.

LIKE its predecessor (Vol I: 1919–1929), this book is indispensable reading for anyone seriously interested in the history of theoretical physics in this century. In addition to his own very significant theoretical contributions, Wolfgang Pauli was one of the “augurs”, as Einstein called them, whose judgement of new ideas is so important for their acceptance or rejection by the physics community. Indeed, Pauli came more and more to assume the role of the “conscience of physics”, now denied Einstein because of his heretical views on quantum mechanics (Pauli’s nickname — “Zweistein” — bears witness to this transfer of *mana*). “No form of approval could be more precious to physicists, not excluding Bohr, than Pauli’s benevolent nodding” Leon Rosenfeld recalled. Not that Pauli’s judgements were always definitive. In 1931, for example, he wrote to Peierls: “About semiconductors, one shouldn’t work on them, it’s a filthy mess [Schweinerei], who knows if semiconductors even exist” (p.94). More often, however, his views prevailed, even when he opposed other “augurs”. His prompt rejection of Bohr’s attempt to explain the continuous energy spectrum of electrons in β -decay (“The idea of a renunciation of energy conservation in the β -spectrum is and remains in my opinion a cheap and quite clumsy philosophy!”, p.4) helped lead Pauli to his greatest triumph: the prediction of the neutrino.

While the first volume of correspondence centred around discussion of the foundations of non-relativistic quantum mechanics, this collection focuses on relativistic quantum mechanics, quantum field theory and what we now call elementary particle physics. Almost half of the 362 letters are exchanges with Heisenberg. Other major correspondents (over ten letters) include Bohr, Dirac, Ehrenfest, Kemmer, Klein, Peierls and Weisskopf. (There is also a 15-item supplement to Vol. I.) Many of the letters deal with technical developments in the evolving quantum theory of fields and should be read in conjunction with the relevant published papers of Pauli and others. Editorial notes to the letters provide references to the papers; the facsimile edition of Pauli’s *Collected Scientific Papers*, and a similar edition of Heisenberg’s *Gesammelte Werke* now being issued, facilitate such comparisons, though one hopes that in future coordin-

ated editions of writings and correspondence will provide cross-references.

The extensive discussion of Dirac’s hole theory makes the absence of an edition of Dirac’s papers keenly felt. Pauli’s unhappiness with the hole theory seems to have been a driving force behind his attempts to develop a quantum field theory in which pair creation would emerge naturally. When he and Weisskopf were able to provide such a theory for scalar bosons, Pauli referred to it as their “anti-Dirac paper” (p.333). Another area in which Pauli was stimulated by dissatisfaction with Dirac’s work was the theory of higher-spin particles. Working with Fierz, Pauli first believed he had shown that such a theory was impossible for particles of spin greater than one, but then realized how to do it.

The only major discussion of the foundations of quantum mechanics in this volume is in response to Einstein’s challenge, in the well-known Einstein–Podolsky–Rosen (EPR) paper, to the completeness of the description of physical reality offered by the theory. Pauli informed Heisenberg of the paper with a characteristic example of his *politesse*: “Einstein has once again expressed himself publicly on quantum mechanics. As you know, this is a catastrophe every time it happens” (p.402). Yet Pauli immediately grasped the importance of the issue of non-separability raised by the paper: “Quite independently of Einstein . . . in a systematic foundation of quantum mechanics, one should start more from the composition and separation of systems . . . This is indeed—as Einstein has correctly sensed—a very fundamental point . . .” (p.404). Pauli encouraged Heisenberg to reply to the EPR paper, which he did in a previously unpublished manuscript printed on pp. 409–418.

While Pauli functioned well as a “conscience of physics”, he never took over Einstein’s role as “conscience of humanity”. His letters are notably shallow in their references to political events of a decade that spanned the world economic crisis, the advent of fascism in Germany and the crises in the Rhineland, Spain, Austria and Czechoslovakia which led to the outbreak of the Second World War. Pauli is clearly opposed to the rise of fascism, as well as the totalitarian turn taken by the Russian Revolution; but his references to such events primarily concern attempts to mitigate the personal difficulties (for some, like Heisenberg) and tragedies (for others, like Kottler) of fellow physicists or relatives, rather than any broader political perspective. The outbreak of the war caught him by surprise: “I didn’t believe in this war up to the last moment . . .” (p.678). His response is revealing of his sense of obligation and his priorities: “I think it is *my* job to take care for the continuation of the spiritual life in a time like the present one” (p.679).

A sampling of the letters suggests that

there are a large number of misprints, including garbled formulae which make certain letters (for example No. 541) difficult to read. There are also numerous misprints in the annotations, particularly in the transcription of English texts which are sometimes unintentionally humorous (Pauli’s broken arm comes from “slipping on a swimming dock” on p. 85; it is soon moved from a “splint into a cling” on p.92).

A great deal of effort has gone into the editorial annotation, much of it to good purpose. However, some questions must be raised. Detailed information about specific references in a letter is often included in an introductory note. This re-

Star cast — Pauli (top, centre) at the Solvay conference of 1927 with Heisenberg on his left. Bohr and Einstein were also present.

quires frequent footnotes to letters directing the reader back to headnotes. One wonders whether it would not have been better to avoid such annoying interruptions by putting the necessary information into the footnotes in the first place. The sheer quantity of annotation shows a curious decay law. In each of the published volumes, about one-half of the pages in the early part is devoted to introductions and footnotes (since these are printed in smaller type than the main texts, this means the ratio of commentary to text is well over one to one). The number of pages of commentary falls off steadily as the volumes progress, until it reaches about 15 per cent of the total near the end. Did the editor’s enthusiasm slacken, was he under pressure to finish off each volume or is there some other explanation? In any case, the total amount of annotation seems excessive, and much could be pruned without great loss to the reader. An editor is under no obligation to share the fruits of *all* his or her research with the reader. One does not really admire a museum where the descriptions furnished by the staff begin to divert attention from the objects to be studied. □

John Stachel, 745 Commonwealth Avenue, Boston, Massachusetts 02215, USA, is Professor of Physics at Boston University, and editor of the *Collected Papers of Albert Einstein*, the first volume of which appears next year.

INTERNATIONAL DICTIONARY OF MEDICINE AND BIOLOGY

No other dictionary approaches this extent of coverage!

The most up-to-date, authoritative and comprehensive dictionary of medicine in English

Available in 3 volumes

0471 01849 X 3300 pages January 1986

Special pre-publication price:
£250.00/\$350.00

After publication:
£285.00/\$395.00

- 150,000 terms — nearly 50% more than any existing dictionary
- Unequalled in depth and scope of coverage across a wide range of specialties
- Standardized, all-inclusive coverage based on contributions from 200 leading experts in their fields who are actively involved in practice
- Extensive cross-referencing to eliminate time-consuming research

Knowledge and technology in the medical and biological sciences have undergone immense changes in the past twenty years. The language used to describe these advances has simultaneously grown and evolved to keep pace with this rapid expansion. Entire new areas have come into existence: technological progress has been made in such fields as advanced imaging techniques, electron microscopy, and biomedical engineering; specialties such as genetics, virology, immunology, and microbiology have experienced important breakthroughs and discoveries leading toward new frontiers; and, far reaching social and public policy developments have affected the language of medicine. The need to avoid confusion and to have easy access to new medical and scientific terminology is more essential than ever. Yet there has been no new major medical dictionary published in English in the past two decades. This groundbreaking new dictionary will set new standards in defining the language of medicine.

New Astronomy Books from **CAMBRIDGE**

Supernovae

PAUL MURDIN and LESLEY MURDIN

This well illustrated volume will make fascinating reading for any astronomy enthusiast. It begins by capturing the flavour of ancient astronomy with a consideration of historical supernovae and then goes on to divulge a wealth of scientific information on supernovae, pulsars and nucleosynthesis in an entertaining and non-technical way.

The Cambridge Astronomy Guide

An Introduction to Practical Astronomy

WILLIAM LILLER and BEN MAYER

The Cambridge Astronomy Guide is intended for lovers of astronomy who wish to do more than just look at the night sky or marvel at glossy pictures of it. Astronomy, more than any other science, offers amateurs the opportunity to make lasting contributions. This guide explains in simple, non-mathematical terms how you can take stunning star photographs and then use the valuable information collected to push forward the frontiers of astronomical science.

- ★ 50 colour plates
- ★ Ben Mayer's odd-numbered chapters provide a humorous account of his progression from raw beginner to one of the world's best known amateur astronomers.
- ★ Bill Liller's even-numbered chapters provide a more extensive commentary of the topics covered by Ben plus some additional material giving the professional point of view.

Astrophotography for the Amateur

MICHAEL COVINGTON

Astrophotography for the Amateur tells you how to take pictures of stars, galaxies, planets, the Moon, the Sun, comets, meteors and eclipses using readily available equipment.

It starts from basics and assumes little knowledge of photography or astronomy, but then goes on to cover the use of cameras in conjunction with telescopes. It constitutes a thorough handbook, including technical information on optical systems, film characteristics and processing techniques. Throughout, the emphasis is on current practice. This book will become the standard handbook for amateur astronomers and will also appeal to photography enthusiasts.

- ★ 127 illustrations (32 in colour)

BioEssays

The monthly review journal
for Molecular, Cellular and
Developmental Biologists –
published for the ICSU Press
by Cambridge University Press

BioEssays was established in mid-1984 to meet the needs of molecular, cellular and developmental biologists for reports of current research in these fields. These appear in the journal's regular features: **What the Papers Say**, **Problems and Paradigms**, and **Science and Society** (with contributions from correspondents in Australia, China, France, Japan, South Africa and the U.S.A).

BioEssays has published over 85 reviews on topics of continuing importance in these rapidly moving fields of biology. Many of the articles encourage reflection and discussion on the implications of the latest findings for science and society.

No other publication in this field gives you as broad a view of what's happening in biology as *BioEssays*!

SUBSCRIPTION INFORMATION

Vol. 4 (January-July 1986) Institutions £34.00;
Individuals £15.00. Air-speeded delivery to most countries.

PLENUM BOOKS: PROBING THE NATURE OF THINGS

DEVELOPMENTAL BIOLOGY

A Comprehensive Synthesis

Volume 1

Oogenesis

edited by **Leon W. Browder**

The inaugural volume in this series provides an integrated review of contemporary research in oogenesis, covering physiological and morphological aspects and the regulation and consequences of gene expression for oogenesis and early development.

0-306-41866-5/646 pp./ill./1985

\$75.00 (\$90.00 outside US & Canada)

HUMAN HYBRIDOMAS AND MONOCLONAL ANTIBODIES

edited by **Edgar G. Engleman**, **Steven K. H. Fountz**, **James Larrick**, and **Andrew Raubitschek**

The first book devoted solely to human hybridomas and monoclonal antibodies. Contributions cover T and B cell hybrids and their applications to infectious diseases, cancer, and autoimmunity. An excellent source on the latest research, complete in methodological detail.

0-306-41982-3/550 pp./ill./1985

\$69.50 (\$83.40 outside US & Canada)

RADIOLABELED CELLULAR BLOOD ELEMENTS

**Pathophysiology, Techniques, and
Scintigraphic Applications**

edited by **M. L. Thakur**

This monograph describes a variety of radiolabeling techniques currently used to trace cellular elements in the bloodstream. Chapters also discuss basic cell physiology and review data on the preparation and use of radiolabeled blood cells. Volume 88 in the NATO ASI Series: Series A: Life Sciences.

0-306-41935-1/proceedings/444 pp./ill./1985

\$69.50 (\$83.40 outside US & Canada)

ENDOCYTOSIS

edited by **Ira Pastan** and **Mark C. Willingham**

A current review of investigations into the mechanisms and processes by which living cells internalize hormones, growth factors, transport proteins, toxins, and viruses.

0-306-41853-3/344 pp./ill./1985

Hubble's constant determined using very-long baseline interferometry of a supernova

§ National Science Foundation, Washington DC 20550, USA

Determination of the angular expansion velocity of the radiosphere of the supernova SN1979c in the galaxy M100 in the Virgo cluster, combined with determination of the radial expansion velocity of the photosphere, yields an estimate of the distance to the Virgo cluster centre of $D_{\text{Virgo}} = 19^{+8}_{-6}$ Mpc and of the Hubble constant of $H_0 = 65^{+35}_{-25}$ km s⁻¹ Mpc⁻¹, where the uncertainties given are based on conservative, but reasonable estimates of all significant errors and are intended to represent 90% confidence intervals.

THE supernova SN1979c in the galaxy M100 (NGC4321) in the Virgo cluster has been emitting several millijanskies of radio radiation at 5 GHz, starting about 1 year after the explosion¹. Figure 1 displays a radio map of the galaxy; the supernova is situated at the southern edge of a spiral arm. Optical spectral analysis² shows that the radial expansion velocity reached values of the order of 12,000 km s⁻¹. At a distance of, for example, 20 Mpc, this expansion velocity is equivalent to a change in the angular diameter of the exploding star of 0.25 arc ms yr⁻¹. Such a rate of change of the angular diameter of a supernova can be monitored with the radioastronomical technique of very-long-baseline interferometry (VLBI), if the presently most sensitive and most widely spaced antennas are used, and if all of them are equipped with the broad band Mark III VLBI system³.

The determination of a supernova's angular expansion rate, coupled with the determination of its radial expansion rate, allows inference of the distance to the supernova and, with its redshift corrected for local streaming motions, inference of H_0 (ref. 4). This article presents such determinations and inferences from observations of the supernova SN1979c. Preliminary results have been given earlier⁴.

VLBI observations

We made VLBI observations of SN1979c at several epochs after the time of explosion, which we assume to be 1 April 1979, about 19 days before maximum light. The observations, and the abbreviations used below, are summarized in Table 1.

At each station a hydrogen maser frequency standard was used to govern the local-oscillator chain and the 'time tagging' of the recorded data. All observations were made with the most sensitive VLBI system available [Mark III in recording mode A (see ref. 3)]. We used a bandwidth of 56 MHz, except for observations involving station Y, whose intermediate-frequency filters limited the bandwidth to 48 MHz. The data were correlated with the Mark III VLBI processor of the Haystack Observatory, located in Westford, Massachusetts.

Each of the observations of SN1979c was straddled by observations of the calibrator sources OJ287 and/or OQ208. With the clock-epoch and clock-rate information determined from the observations of the calibrator sources, we limited the search for fringes of the supernova to delay and delay-rate ranges that corresponded to windows on the sky with widths as narrow as possible but of at least 1 arc s in extent. The window

centres corresponded to the supernova position determined previously with the VLA⁶. (The positions of many celestial sources determined with the VLA (Very Large Array) agree with those determined by VLBI to within 0.3 arc s; see ref. 5 for comparison of position determinations.) The narrow search windows allowed the reliable detection of far weaker fringes than is possible when the search must extend over many independent delay and delay-rate channels to account for uncertainties in the relative clock epochs and rates (see ref. 7).

When fringes were detected, we used the corresponding information to narrow the search windows even further. In cases where fringes were detected with two two-element interferometers of a triplet of antennas, closure observables were calculated for the third two-element interferometer. The values of these observables have a probability of ~1% of being due to noise alone. For observations of SN1979c on 1 December 1983, these procedures allowed us to quadruple the number of detections relative to the number obtainable with 'normal' processing. From observations on 9 May 1983, at 8.4 GHz, we detected the source only with the BM interferometer. For the DM interferometer, we determined a 3σ upper limit ($\sigma \equiv 1$ statistical standard deviation) for the correlation coefficient, a value that corresponds to a probability of 10% that noise somewhere in the search area of 0.3×0.6 arc s would exceed this upper limit. The other upper limits were ignored in the further analysis, as they were too high to be of use.

The correlation coefficients were corrected for any coherence losses and for the bias arising from the fact that they are always positive⁸, and were calibrated to yield correlated flux densities⁹.

Fig. 1 Radio map of the galaxy M100 showing the supernova SN1979c [$\alpha(1950.0) = 12^{\text{h}} 20^{\text{m}} 26.71^{\text{s}}$, $\delta(1950.0) = 16^{\circ} 04' 29.5''$] situated at the southern edge of one of the galaxy's spiral arms. The contour levels are at 2.5, 5.0, 7.5, 10, 20, 30, 50, and 80% of the peak flux density per beam area of 9.75 mJy.

|| Present addresses: Siemens AG, Postfach 700074, München, FRG (J.M.M.); E. O. Hurlburt Centre for Space Research, Naval Research Laboratory, Washington DC 20375-5000, USA (K.W.W.).

Table 1 Observations of SN1979c

Date of observation	Radio frequency (GHz)	Polarization*	Antennas†	MSIA‡	Sensitivity§ of MSIA (7 σ) (mJy)	No. of scans with MSIA
8 December 1982	5.0	LCP	BGOY	BY	1.7	4

31 May 1984	1.7	LCP	BGOY	BY	1.4	5

According to Weiler *et al.*⁶, the coordinates of SN1979c are: α (1950.0) = 12 h 20 min 26.71 s, δ (1950.0) = 16°04'29".5.

* LCP, Left-hand circular polarization. RCP, Right-hand circular polarization.

† B, 100-m antenna in Effelsberg near Bonn, FRG; belongs to the Max-Planck-Institut für Radioastronomie. We give for each antenna a representative value of the product, S_{sys} , of system temperature and inverse sensitivity in Jy for each of the frequencies in GHz: S_{sys} (1.7, 2.3, 5.0, 8.4) = 28, 260, 47, 150. D, 64-m antenna in Goldstone, California, USA; belongs to NASA. S_{sys} (2.3, 8.4) = 29, 45. F, 25-m antenna in Ft Davis, Texas, USA; belongs to Harvard College Observatory. S_{sys} (2.3) = 1,650. G, 43-m antenna in Green Bank, West Virginia, USA; belongs to the National Radio Astronomy Observatory. S_{sys} (1.7, 2.3, 5.0) = 66, 590, 190. K, 37-m antenna in Westford, Massachusetts, USA; belongs to the Northeast Radio Observatory Corporation. S_{sys} (2.3, 5.0, 8.4) = 5900, 650, 800. M, 64-m antenna near Madrid, Spain; belongs to NASA. S_{sys} (2.3, 8.4) = 36, 50. O, 40-m antenna near Big Pine, California, USA; belongs to California Institute of Technology. S_{sys} (1.7, 2.3, 5.0) = 235, 425, 300. S, 25-m antenna in Onsala, Sweden; belongs to Onsala Space Observatory. S_{sys} (2.3) = 1,000. Y, Equivalent to a ~130-m antenna (~26 × 25 m antennas of the VLA 'phased up') near Socorro, New Mexico, USA; belongs to the National Radio Astronomy Observatory. S_{sys} (1.7, 5.0) = 26, 27. All two-element interferometers with the symbol for at least one antenna in parentheses failed to yield fringes.

‡ Most sensitive two-element interferometer of array.

§ Maximum sensitivity for coherent integration of 12 min and a bandwidth of 50 MHz. Here and hereafter, 1 σ denotes one statistical standard deviation.

|| One scan consists of an observing time of ~12 min using a bandwidth of ~50 MHz.

Table 2 Parameter estimates for SN1979c

Date of observation	Time since explosion* (yr)	Frequency (GHz)	$S_{\text{tot}}^{\text{VLA}†}$ (mJy)	S_{tot} (mJy)	Angular diameter‡ (mas)
8 December 1982	3.691	4.99	5.5 ± 0.3	5.30 ^{+0.26} _{-0.54}	1.05 ^{+0.09} _{-0.10}
9 May 1983	4.117	2.29	—	9.7 ^{+0.8} _{-0.4}	1.67 ^{+0.26} _{-0.12}
9 May 1983	4.117	8.42	3.9 ± 0.2	3.8 ^{+0.2} _{-0.2}	>0.91
1 December 1983	4.672	4.99	4.2 ± 0.2	4.08 ^{+0.45} _{-0.38}	1.43 ^{+0.07} _{-0.07}
31 May 1984	5.173	1.67	7.9 ± 0.6	7.75 ^{+0.61} _{-0.63}	2.16 ^{+0.44} _{-0.50}

* The assumed date of explosion is 1 April 1979.

† The total flux density of the supernova measured with the VLA alone. For the 5-GHz data, the errors were taken to be 5% of the total flux density so as to include both statistical standard deviations and possible systematic errors. For the 1.7-GHz data, the error represents the variation of the total flux densities determined from observations of the source on 31 May 1984 and 1 June. In all four cases, the 1 σ noise level in apparently blank fields of the maps near the position of the supernova is more than three times smaller.

‡ Estimated angular diameter for a uniform sphere model of the brightness distribution of the supernova. For the meaning of the errors, see text.

The calibration procedure was checked for our observations of the calibrator sources, which have relatively simple brightness distributions, and was found to yield flux densities consistent with the predictions from a 'best-fit' circular gaussian brightness distribution to within $\pm 7\%$ in each case.

Angular diameter determinations

The angular diameters of the supernova at the epochs of our observations were all small compared with the smallest fringe spacing obtainable with our arrays. Hence, the radio brightness distribution of the supernova cannot be well determined from our VLBI data. Further, because of the low declination of SN1979c and the mainly east-west orientation of our VLBI arrays, the highest resolution in the north-south direction was about four-fold lower than that in the east-west direction, making any (small) deviations of the brightness distribution from circular symmetry difficult to discern.

Under these circumstances, any angular diameter of the supernova inferred from the VLBI data will be strongly model-dependent. We, therefore, considered a range of plausible possibilities, assuming that any given model, if applicable at all, would be applicable for all of our epochs of observation. Clearly, a model in which the brightness is distributed in a thin circular ring, normal to our line-of-sight, will lead to the smallest inferred angular diameter. By contrast, a model in which the brightness is highly concentrated near the centre will yield a relatively large value for the inferred angular diameter.

We take as an example an optically-thin uniform-sphere

model. From the correlated flux densities, S_{corr} , from each epoch of observation, we estimated by weighted-least-squares the total flux density, S_{tot} , and the angular diameter, θ_{us} , as well as the standard errors in these estimates implied by the statistical standard errors of S_{corr} . The values of S_{corr} were normalized by dividing by S_{tot} and plotted together with the predictions of the model in Fig. 2.

We estimated crudely the contribution of possible calibration errors to the uncertainties of the parameter estimates by changing, in turn, the sensitivity of each antenna of the array by $\pm 15\%$ while keeping the sensitivities of the other antennas fixed. We consider this choice of the value for the uncertainty of the antenna sensitivities to be conservative in view of our check of the calibration procedures for the calibrator sources, mentioned above. The largest variations in the estimated parameters due to the changes of the sensitivities of the antennas were twice as large as the corresponding statistical standard deviations. For the uncertainty of each parameter estimate, we adopted the root-sum-square (r.s.s.) of the value of the largest variation and the statistical standard deviation. The results of the analysis are given in Table 2.

To check the sensitivity of our results to the choice of antennas, we repeated the analysis with data from subsets of antennas. The estimated parameters from this analysis were reasonably consistent with the parameter values obtained from the analysis of all the data⁴.

We also tried to check for any significant deviation from circular symmetry by using elliptical gaussian models. For each

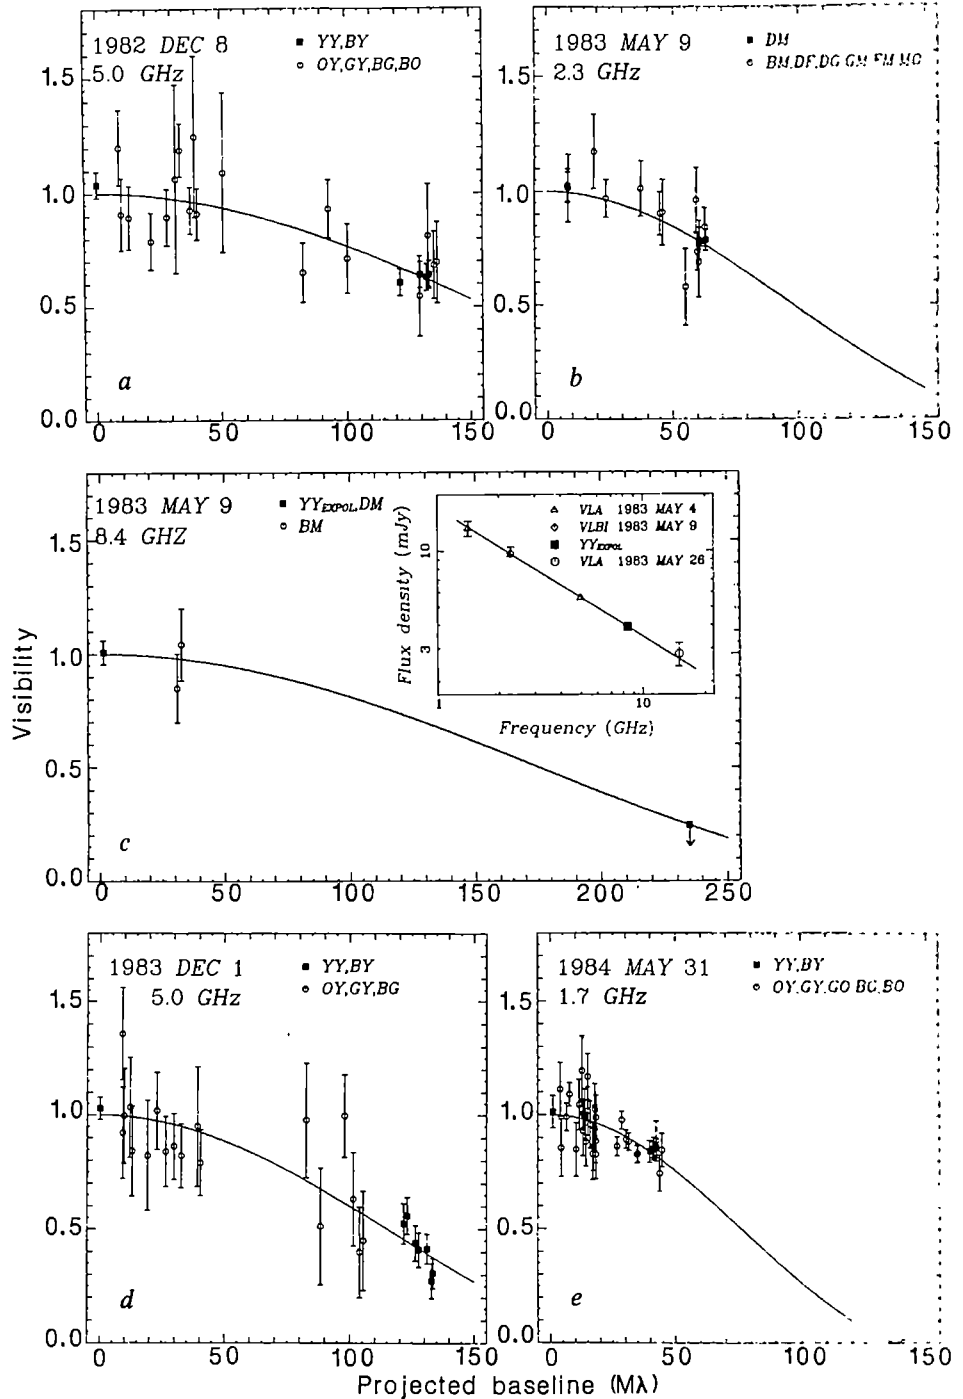

Fig. 2 *a-e*, Measured visibility amplitudes and predictions from the fit of a uniform sphere model. The filled squares show the most significant data points. Antenna pairs are listed in order of increasing baseline length. The symbol YY indicates the values for the total flux density measured with the VLA. The inset of Fig. 2*c* shows the weighted-least-squares fit to the spectral index, $\alpha = -0.69 \pm 0.06$ ($S_\nu \propto \nu^\alpha$), from the values of the total flux density at 1.5 and 5 GHz obtained at the VLA (ref. 1) and at 2.3 GHz obtained with our VLBI array 5 days later. The filled square shows the value for the flux density extrapolated with this power law to $\nu = 8.42$ GHz. This value is used as the zero-baseline correlated flux density (YY_{EXPOL}) in Fig. 2*c*. Also shown is the data point at 15 GHz obtained with the VLA (ref. 1) ~ 3 weeks later.

set of 5-GHz observations of the supernova, the ratio of the estimates of the major and minor axes was unity to within 1σ ; however, 1σ for these ratios was as large as ~ 2.5 . A higher north-south angular resolution is needed to determine, or to derive a useful upper bound on, any deviation from circular symmetry the source might have.

We also computed closure phases to search for evidence for asymmetry of the radio structure of the supernova. However, the closure phases were randomly scattered, thereby indicating no significant departure from zero. This result is also consistent with, but not conclusive evidence for, the supernova being circularly symmetric.

For a circular-gaussian model for the brightness distribution, the angular diameter at half maximum is 1.81 times smaller than θ_{us} , and at 10% of maximum about equal to θ_{us} . A thin ring, as stated above, gives the smallest diameter, 1.65 times smaller than θ_{us} . Optically thin shells give diameter determinations intermediate between those of a thin ring and a uniform sphere;

for example, for a uniform shell of thickness 5–25% of the outer radius of the shell, the diameter becomes, respectively, 1.34–1.24 times smaller than θ_{us} (see refs 10, 11).

An optically-thick shell or sphere, which is equivalent to a uniform disk, yields a diameter determination $\sim 10\%$ smaller than θ_{us} . However, since the time of our first VLBI observations, the radio spectrum of the supernova has had a spectral index, $\alpha(S_\nu \propto \nu^\alpha)$ of ~ -0.6 (ref. 12), indicating that the radio source is optically thin. Optically thick sources can therefore be ignored, but in any event do not extend the uncertainty of our diameter estimates.

An optically-thin shell of emission is favoured by Chevalier¹³, who assumes the radio radiation is synchrotron emission from the interaction of the supernova shock front with a circumstellar medium created by presupernova mass loss. The classical supernova remnant with a shell of emission is Cas A (see, for example, ref. 14). With $\sim 80\%$ of all supernova remnants (SNRs) being conventionally represented as shell-type models¹⁵, the shell

geometry seems to be the standard for the radio emission for epochs at least several hundred years after the supernova explosion.

An optically-thin uniform sphere of emission, similar to a centre-filled remnant, that is, a plerion, could be expected from one type¹⁶ of centrally driven models (refs 16, 17; see also ref. 18). The classical SNR of plerionic morphology is the Crab nebula. Only a few such examples have yet been found¹⁵. Moreover, plerionic SNRs have flatter spectra ($\alpha > -0.3$) than shell-like SNRs, which have $\alpha \sim -0.45$ (ref. 15), and thus may be less closely related to SN1979c than shell-like SNRs, if evolutionary effects on the geometry and the spectrum of a remnant do not make such comparisons irrelevant.

A ring of emission for SNRs has recently been suggested by Manchester¹⁹, who assumes interaction of a rotating pulsar beam of particles with the medium close to the boundary of the SN ejecta. We include such a geometry in estimating the uncertainty of our diameter determinations of SN1979c.

Considering all of these possibilities, we conclude that the diameters inferred from the uniform sphere and the thin ring probably straddle the actual diameter, which is likely to be that of an optically-thin shell.

Time dependence

The values for the angular diameters, θ , of the supernova for both the uniform sphere and the ring models are plotted in Fig. 3 as a function of time. The results from the 5-GHz data indicate that, with high probability, the supernova is expanding. These results, combined with the zero diameter at the time of explosion, allow the deceleration (or acceleration) to be estimated from an assumed time dependence of the angular diameter: $\theta \propto t^m$ (see refs 20, 21). Taking the standard errors for the angular diameter determinations to be independent yields the result $m = 1.3 \pm 0.5$.

Deceleration of the expansion of the supernova would be expected for the shock-front model, and evidence for it has been found in shell-type SNRs (see ref. 22). In contrast, acceleration of the expansion would be expected for the centrally-driven model and some evidence for weak acceleration has been found in the Crab nebula²³. However, neither the accuracy nor the number of our measurements is yet sufficient to discriminate between these models on the basis of our estimate of the parameter m . More observations at later epochs are required to determine with useful confidence any deviation of m from unity.

Frequency dependence

The value we obtained for the angular diameter at 2.3 GHz is significantly larger than the value for the diameter at 5.0 GHz when compared at the same epoch (we assume $m = 1$). The value at 1.7 GHz, because of its relatively large uncertainty, and the lower bound at 8.4 GHz, are both consistent with the diameter's not being a function of frequency.

Is this frequency dependence inherent to the supernova or could the angular diameter be broadened noticeably by scattering in the propagation medium? From a survey of pulsar interstellar scintillation, Cordes *et al.*²⁴ predict that the scattering angle, θ_{scat} (FWHM of a gaussian), of a source at the supernova's galactic latitude, $|b^{\text{II}}| = 77^\circ$, is between 170 and 340 arc μs for 1.7 GHz and scales as $\theta_{\text{scat}} \propto \nu^{-2.2}$. To calculate the effect of θ_{scat} on the estimate of θ_{us} , we multiply θ_{scat} by 1.81 to convert its value to that of the 'equivalent' uniform sphere. Thus, we could, at $\nu \geq 5$ GHz, essentially exclude any broadening of the angular diameter and at $\nu \sim 2.3$ and 1.7 GHz expect broadening of no more than 2 and 4%, respectively. However, if we use weighted least squares to fit to the observed data a function of the form, $\theta_{\text{us}}^2(\nu, t) = 1.81^2 \theta_{\text{scat}}^2(\nu) + \theta_{\text{us}}^2(t)$, with $\theta_{\text{scat}} \propto \nu^{-2}$ and $\theta_{\text{us}} \propto t$ as plotted in Fig. 3, we obtain a good fit and a value for θ_{scat} (1.7 GHz) of 1.1 arc ms, which is about three-fold larger than the above upper bound of Cordes *et al.* In fact, VLBI determinations by Resch²⁵ at 74, 111, and 196 MHz of angular diameters of extragalactic sources, situated within $\sim 20^\circ$ of SN1979c indicate $\theta_{\text{scat}} \propto \nu^{-n}$ with $n < 2$ and values for θ_{scat} much larger than

Fig. 3 The angular diameter determinations assuming two (extreme) models of the brightness distribution. The solid straight line represents a least-squares fit to the assumed zero-point origin and the two 5-GHz values. The 1.7 and 2.3-GHz values are probably subject to broadening by scattering in the propagation medium (see text).

1 arc ms when extrapolated to 1.7 GHz. Also, as Cordes *et al.* noted, some values of Resch exceeded by up to a factor of 1.6 their upper bounds even when a scattering law of $n = 2.2$ was assumed. We thus conclude that our estimate of θ_{scat} is within the range of others' estimates and that our diameter determinations at 2.3 and 1.7 GHz could have been significantly broadened by scattering in the propagation medium, but that our determinations at 5.0 and our lower bound at 8.4 GHz could not. If the angular diameter at the lower frequencies is indeed broadened by scattering, the difference between the diameter determinations at different frequencies should decrease as the source expands; future observations at more than one (low) frequency could help to resolve this issue.

Distance to M100 and Hubble's constant

To estimate the distance to SN1979c, we combine our radio determination of the supernova's angular expansion velocity with optical determinations of the radial expansion velocity. We first list the main assumptions used in making this estimate: (1) the widths of optical spectral lines reflect expansion of the supernova's photosphere; (2) the expansions of the photosphere and the radiosphere are each isotropic within a factor $\mu = 1.0 \pm 0.15$; (3) the expansion velocity of the radiosphere equals that of the outer boundary of the supernova's shock front and is, for at least 1 yr after the explosion, a factor of $\eta = 1.2 \pm 0.2$ greater than the expansion velocity of the photosphere; and (4) the angular diameter θ of the radiosphere can be described by $\theta \propto t^m$, with t the time since explosion and m constrained by $m \leq 1$ (no acceleration allowed).

The first assumption is based on the finding that in the early stages of supernova evolution the time dependences of the inferred photospheric temperature and the received flux are both consistent with an expanding black body (see, for example, ref. 26). However, to some extent, the broadening of the lines may also be caused by other processes, for example, turbulence in the emission region.

The second assumption is supported by observations that most young and medium aged SNRs are approximately circularly shaped (ref. 27 and refs therein) and by the likelihood that the degree of circular symmetry for supernovae is even higher. In the future, for the photosphere, optical spectropolarimetry might reveal any anisotropic expansion at least in the early stages of a supernova's evolution^{28,29}. For the radiosphere, any deviations from non-isotropic expansion in the plane of the sky could, in principle, be determined accurately through VLBI by mapping the brightness distribution of the supernova, but our present data cannot yield useful determinations. Our assumed uncertainty for μ is consistent with observations of most SNRs and with inferences for supernovae.

The third assumption is based on the fact that charged particles are accelerated in shock front regions and thus are likely

to radiate radio waves. In the shock front model, the radiosphere is a shell of emission with its outer radius being equal to the outer radius of the supernova's shock front and its inner radius equal to the radius of the (H α) photosphere³⁰. In centrally driven models, the radio radiation emanates from the shock front¹⁷ or predominantly from inside the shock front shell¹⁶. For the latter case, the photospheric material is assumed to have developed a filamentary structure very soon after the explosion as otherwise the opacity of the material would prevent penetration of radio radiation³¹. We do not discuss here the likelihood of such a process; rather we assume that any emission region inside the shock front shell is not concentrated near the center but is described by a uniform sphere with its expansion velocity linked to that of the photosphere such that $\eta \geq 1$.

What is the expansion velocity of the photosphere? Optical and ultraviolet spectra of SN1979c were obtained at several epochs^{2,32-35}. The dominant profile in the optical spectrum is the H α emission line. The blue extension of this line indicates expansion velocities of (ref. 2) $\sim 10,500 \text{ km s}^{-1}$ on 28 May, 26 June and 19 November 1979, and (ref. 35) $\sim 9,000 \text{ km s}^{-1}$ on 10 April 1980. The minima of the absorption troughs of the P Cygni profiles of the ultraviolet and optical lines other than H α indicate expansion velocities between $\sim 8,800$ and $10,000 \text{ km s}^{-1}$ in the period between 22 April and 1 July 1979 (refs 2, 33). According to Kirshner³⁵, all these values define the expansion velocity of the photosphere; the maximum expansion velocity of supernova ejecta is larger. The blue edge of the absorption trough in the He I $\lambda 5,876/\text{Na I D}$ profile, in spectra taken between 22 April and 26 June 1979, reveals a velocity of $\sim 12,000 \text{ km s}^{-1}$ (ref. 2); this value probably defines the expansion velocity of the outer boundary of the supernova's shock front. Considering these various results, we adopt a value of $v_{\text{ph}} = (9 \pm 1) \times 10^3 \text{ km s}^{-1}$ for the expansion velocity of the photosphere for an epoch, say, 1 yr following the explosion, and a value of $\eta v_{\text{ph}} = (11 \pm 2) \times 10^3 \text{ km s}^{-1}$ for the expansion velocity of the radiosphere at this epoch, consistent with the maximum expansion velocity of the supernova ejecta (for $0.8 \leq m \leq 1.0$; see below).

The fourth assumption allows for the expansion velocity of the shock front to vary with time. The parameter m was estimated to be ≥ 0.89 from the change of the width of H α ³⁶, and ≥ 0.90 from the radio light curve³⁷, both values consistent with the inference from our VLBI observations. More VLBI observations are needed not only to determine m more accurately, but also to test our assumption that a simple power law represents adequately the expansion of the radiosphere. In fact, the range of values of m consistent with the present VLBI observations is so great as to be in large part inconsistent with assumptions (3) and (4), when the latter are coupled with the estimates, discussed above, of expansion velocities inferred from optical spectra.

Using the (assumed) relation between the velocities of expansion of the radiosphere and the photosphere at an epoch, t_{ph} , 1 yr after the supernova explosion, to determine the proportionality constant in the (assumed) relation $\theta \propto t^m$, and the relation $\theta_{\text{ph}} = 2v_{\text{ph}}/D$, where θ_{ph} is the angular velocity of expansion of the photosphere at that epoch, v_{ph} the corresponding (radial) expansion velocity, and D our distance from the supernova, we obtain by simple algebra:

$$D = \frac{2\mu\eta v_{\text{ph}} t}{\theta m} \left[\frac{t}{t_{\text{ph}}} \right]^{m-1}$$

With $\eta v_{\text{ph}} = (11 \pm 2) \times 10^3 \text{ km s}^{-1}$ on, say, 10 April 1980 (that is, $t_{\text{ph}} = 3.2 \times 10^7 \text{ s}$), with m restricted to $m = 0.9 \pm 0.1$, and with $\theta = 1.0 \pm 0.25 \text{ arc ms}$ (see Fig. 3) at $t = 1.35 \times 10^8 \text{ s}$, the epoch midway between our two 5-GHz data points, we obtain for SN 1979c: $D_{\text{SN1979c}} = 19^{+8}_{-6} \text{ Mpc}$. If we further assume that SN 1979c is in M100 (Fig. 1) and that the distance to M100 is within 10% of the distance D_{Virgo} to the centre of the Virgo cluster, since M100 is within 6° of this centre and has a redshift consistent with this location, we get:

$$D_{\text{Virgo}} = 19^{+8}_{-6} \text{ Mpc}$$

The range of uncertainty given is intended to represent the 90% confidence interval and is based on the assumption that each of the parameters in the above expression for D contributes independently.

A value of Hubble's constant, H_0 , can be obtained by combining our distance estimate with determinations of the mean (radial) velocity, v_0 , of Virgo away from the centre of the Local Group and the correction for the infall (radial) velocity, v_{infall} , of the centre of the Local Group towards Virgo: $H_0 = (v_0 + v_{\text{infall}})/D_{\text{Virgo}}$. Unfortunately, $v_0 + v_{\text{infall}}$ is not well determined. Considering the spread in the various published values for v_{infall} , based on observations of galaxies (see refs 38-43), as well as the equivalent values estimated from the anisotropy of the microwave background⁴⁴⁻⁴⁶, and the different estimates of v_0 (see refs 47-49), we take $v_0 + v_{\text{infall}} = 1,250 \pm 150 \text{ km s}^{-1}$ and obtain

$$H_0 = 65^{+35}_{-25} \text{ km s}^{-1} \text{ Mpc}^{-1}$$

where the range of uncertainty given is dominated by that for D_{Virgo} and is also intended to represent the 90% confidence interval.

Comparing our estimates with those obtained by de Vaucouleurs⁵⁰ ($D = 11.8 \text{ Mpc}$ for M100, equivalent to $H_0 \sim 100 \text{ km s}^{-1} \text{ Mpc}^{-1}$) and by Sandage and Tammann^{51,52} ($D = 22.2 \text{ Mpc}$ for M100, equivalent to $H_0 \sim 50 \text{ km s}^{-1} \text{ Mpc}^{-1}$), we find that our estimates are nearly midway between theirs but hardly distinguish between them.

More, and more accurate, VLBI measurements on SN1979c and other supernovae should allow us to improve the determinations of θ , m , and μ . However, we have not yet conceived of any purely observational means to relate the photosphere and the radiosphere. The uncertainty in this relation will therefore likely dominate the uncertainty in any estimate of H_0 based on the method described here, until the relation can be reliably modeled or until optical interferometry, perhaps from earth orbit, can be used to measure directly the angular size of a supernova's photosphere.

Conclusion

VLBI observations of SN1979c in the galaxy M100 yielded estimates of the angular size of the supernova. These measurements were used, together with other information, especially from the optical spectra, to estimate the supernova's distance and Hubble's constant. The range of the uncertainties of our estimates can probably be decreased with new and more sensitive VLBI observations of SN1979c in the near future. The sensitivity can be increased by recording the data on longer tapes, thus allowing longer integration times. It can also be increased by including in the array the 305-m diameter antenna at Arecibo. This antenna's low latitude would increase our north-south resolution two-fold and might enable us either to determine the brightness distribution of SN1979c or, at least, to measure, or place useful bounds on, its deviation from circular symmetry.

Observations of SN1979c at 5 GHz at a third epoch would probably be useful for a more accurate determination of the deceleration (or, possibly, acceleration) of the expansion. More observations at lower frequencies would allow more detailed investigation of whether the apparent source diameter is broadened by scattering in the propagation medium.

About one supernova per year should be detectable with our present VLBI system. Moreover, the Hubble Space Telescope should allow measurement of supernova spectra at the same epochs at which VLBI techniques could be used to measure the angular size of the supernova. Combining such measurements should enable us to determine distances to galaxies as far away as $\sim 40 \text{ Mpc}$. Observing supernovae in many different directions will allow us to study statistically the deviations of their (radial) velocities from the Hubble flow and thereby provide an indication of the accuracy of our inferred value of H_0 .

Our method is the fourth that makes use of supernovae as distance indicators (for descriptions of the other three, see refs 53-56). Each has its difficulties, but each may be useful for deriving distance estimates at least partially independent of the

others and thereby for allowing useful redundancy in the estimates of Hubble's constant.

We thank R. J. Bonometti and N. L. Cohen for help with observations in May 1983, and M. I. Ratner for valuable discussions. N.B., M.V.G., and I.I.S. were supported in part by the NSF under grant no. AST-8300796. The Haystack Observatory

Magnetic confinement of a neutral gas

R. V. E. Lovelace, C. Mehanian, T. J. Tommila* & D. M. Lee

Department of Applied Physics, Department of Physics, and Laboratory of Atomic and Solid State Physics, Cornell University, Ithaca, New York 14853, USA

A three-dimensional dynamic trap for confining a collisional neutral gas is described. The trap uses the interaction of the magnetic moments of the gas atoms with a time-dependent magnetic field. Collisions lead to the evaporative cooling of the trapped atoms and to the viscous heating of the gas, particularly at high densities. This magnetic trap may allow the attainment of Bose-Einstein condensation in spin-polarized atomic hydrogen gas.

THE dynamic magnetic confinement of a neutral gas by the interaction of the magnetic moments of the gas atoms with a magnetic field including a rapidly oscillating component creates a magnetic trap which may provide a means of producing a Bose-Einstein condensation in a spin-polarized atomic hydrogen gas.

Fritz London¹ was the first to consider the phenomena of superconductivity in metals and superfluidity in liquid ⁴He in terms of quantum mechanics on a macroscopic scale. Since then, superfluidity has been found to occur in liquid ³He below 3 mK (ref. 2), and it is thought to occur in neutron stars³. The recently achieved stabilization of spin-polarized atomic hydrogen gas in strong magnetic fields (9 T) and at low temperatures (100-500 mK) presents a possible new opportunity to observe macroscopic quantum phenomena^{4,5}. Because hydrogen atoms behave as bosons, the macroscopic manifestations of Bose-Einstein condensation are expected to lead to a variety of interesting

quantum properties in this dilute, weakly interacting Bose-Einstein gas. The occurrence of Bose-Einstein condensation in an ideal Bose gas is governed by the equation

$$T_c = [h^2 / (2\pi m k_B)] (n / 2.61)^{2/3}$$

where T_c is the critical temperature, n is the particle density, m is the particle mass, h is Planck's constant, and k_B is Boltzmann's constant. Sufficiently high densities and low temperatures must be attained in order to have a Bose-Einstein condensation. Table 1a shows densities and temperatures corresponding to the onset of Bose-Einstein condensation.

Spin-polarized atomic hydrogen gas is formed by collecting atoms in the two low-energy hyperfine Zeeman states (the 'a' and 'b' states, where the electron spin is antiparallel to the magnetic field) in a strong magnetic field at low temperatures⁶. Atoms in these two states are forced towards regions of stronger magnetic field, while atoms in the two high-energy hyperfine states (the 'c' and 'd' states, where the electron spin is parallel to the magnetic field) are forced towards low-field regions. The 'a' state is a mixed state whose wavefunction includes a small

admixture of the electronic spin-up state causing recombination of atoms to molecules in three-body, singlet interaction collisions (where the helium-coated surfaces of the confinement vessel may play the role of the third body). As a consequence, the sample loses its 'a' state population as time progresses, leaving only the pure 'b' state atoms whose nuclei and electrons are polarized parallel to one another (and therefore, have a triplet interaction). Because of the long longitudinal relaxation time (T_1) between the 'b' and the 'a' states, the resulting doubly polarized sample would be relatively long lived^{7,8}, and thus ideal to produce the high-density sample needed to fulfill conditions for Bose-Einstein condensation were it not for the three-body dipole recombination which becomes important at densities above 10^{18} cm⁻³ (refs 9-14). One possible solution is to obtain Bose-Einstein condensation at temperatures below 10 mK, where the required gas phase densities are less than 10^{17} cm⁻³. Unfortunately, at these temperatures surface densities are high even for liquid helium film surfaces (binding energy ~ 1 K), so that surface three-body dipole recombination destroys the gas rapidly⁹⁻¹⁴.

An alternative approach is to remove the influence of surfaces by constructing a three-dimensional magnetic trap¹⁵⁻¹⁷. Static magnetic field minimum traps are possible, but only for the 'c' and 'd' state atoms, which are low-field seekers¹⁵. One could inject a 'b' state gas and use electron spin resonance to flip the electron spins so that the resulting 'c' state atoms would be magnetically confined. However, dipole-dipole interactions are predicted⁹ to cause a rapid flipping of the electron spins and this would lead to a rather rapid loss of the sample. (Note that a variety of three-dimensional electromagnetic traps have been used for the collisionless confinement of small numbers of ions¹⁸.)

Here we investigate a three-dimensional dynamic magnetic trap, where the magnetic field includes a 'fast' time-dependent component. The dynamic trap must provide containment in the presence of frequent collisions. (Thus, one can rule out confinement in a rotating magnetic mirror field where the possible stable single-particle motion is analogous to that of the Trojan asteroids¹⁹.) A simple dynamic trap which is viable in the presence of collisions can be made by passing an alternating current through a circular wire loop located with its axis parallel to a strong uniform static magnetic field. This magnetic field oscillates between a mirror and an anti-mirror configuration and provides containment for the high-field-seeking 'a' and 'b' state atoms (as well as for the 'c' and 'd' state atoms). Here we first analyse the collisionless confinement of a single atom, then investigate the influence of collisions using the classical Boltzmann transport equation and a Monte-Carlo code for the numerical evaluation of particle orbits including collisions. (A quantum-mechanical, mean-field treatment of a collisional gas confined in a dynamic trap²⁰ confirms the classical treatment for temperatures above T_c .) Next, a treatment is given of the evaporative loss of atoms and heat from the trapped gas, and of the viscous heating of the gas. A method is described for filling a dynamic trap using the evaporative cooling which can be enhanced by gradual reduction in the depth of the magnetic well. This may allow the attainment of the conditions for Bose-

Einstein condensation. An alternative approach to Bose-Einstein condensation using a magnetic field and evaporative cooling has recently been proposed by Hess²¹. Finally, we discuss some of the anticipated problems of filling the trap and of observing the Bose-Einstein condensation in a spin-polarized atomic hydrogen gas.

Single-particle motion

The envisaged temporal variations of the magnetic field $\mathbf{B}(\mathbf{x}, t)$ are very much slower than the electron spin precession period. Thus, the potential describing the interaction of the atom with the magnetic field is

$$V(\mathbf{x}, t) = -\mu|\mathbf{B}(\mathbf{x}, t)|$$

where μ is the magnetic moment of the atom. For the case of spin-polarized atomic hydrogen, $\mu \approx \hbar e/(2m_e c) \approx 0.93 \times 10^{-20}$ erg G⁻¹ (or 0.93×10^{-23} J T⁻¹), where m_e is the electron mass. Note that the magnetic moment is parallel to \mathbf{B} for the 'a' and 'b' states of atomic hydrogen so that $\mu > 0$. For the 'c' and 'd' states it is antiparallel and $\mu = -|\mu|$. In the absence of collisions, the equation of motion for an atom of mass m is

$$m \frac{d^2 \mathbf{x}}{dt^2} = -\nabla V \quad (1)$$

In a static field $\mathbf{B}(\mathbf{x})$ a spin-polarized atom with μ parallel to \mathbf{B} (the 'a' or 'b' states of hydrogen) tends to move towards regions of maximum $|\mathbf{B}|$. There are, of course, no isolated maxima of $|\mathbf{B}|$ in free space (Earnshaw's theorem; see, for example, ref. 22).

The magnetic field $\mathbf{B}(\mathbf{x}, t)$ is considered to consist of a uniform, time-independent component $B_0 \hat{z}$ (with $B_0 > 0$), and the time-dependent field $\mathbf{b}(\mathbf{x}, t)$ of one or more circular wire loops with axes coinciding with the z -axis. We consider the case of a single wire loop of radius R . We assume $b^2 \ll B_0^2$ so that $|\mathbf{B}| \approx B_0 + b_z$. In the vicinity of the centre of the loop, we have

$$b_z = b_0(t) \left\{ 1 + \frac{3}{4} \left(\frac{r}{R} \right)^2 - \frac{3}{2} \left(\frac{z}{R} \right)^2 + \dots \right\}$$

where $r^2 = x^2 + y^2$, $b_0(t) = 2\pi I(t)/(cR)$ in gaussian units [or $\mu_0 I/(2R)$ in MKS units], and I is the current in the wire loop. For $b_0 < 0$ the field configuration corresponds to a mirror field, whereas for $b_0 > 0$ it is an anti-mirror configuration. The Taylor expansion simplifies the immediate discussion; the exact field of a circular loop is used subsequently. From equation (1),

$$\frac{d^2 x}{dt^2} = -\alpha(t)x, \quad \frac{d^2 y}{dt^2} = -\alpha(t)y, \quad \frac{d^2 z}{dt^2} = 2\alpha(t)z \quad (2)$$

where $\alpha(t) \equiv (3/2) [\mu b_0(t)/(mR^2)]$. Evidently, the sign of μ is irrelevant if $b_0(t)$ is an oscillatory function with an average value of zero.

Exact solutions to equations (2) exist for the case where $b_0(t)$ or $\alpha(t)$ has a square wave dependence, that is, $\alpha(t) = \alpha_0 \text{sign}[\sin(\omega_e t)]$, where α_0 and ω_e are constants. This case is evidently the temporal analogue of an alternating-gradient or

strong focusing synchrotron²³. The motion in the x, y or z directions can be written down explicitly during the intervals in which $\alpha(t)$ is positive or negative. Thus, the phase space location at some time t for, say, the z motion, $[z(t), \dot{z}(t)/(2\alpha_0)^{1/2}]$, can be expressed as a product of matrices multiplying the initial location $[z(0), \dot{z}(0)/(2\alpha_0)^{1/2}]$. For each interval with $\alpha < 0$ or $\alpha > 0$ there is a matrix factor

$$\begin{pmatrix} \cos(\psi) & \sin(\psi) \\ -\sin(\psi) & \cos(\psi) \end{pmatrix} \text{ or } \begin{pmatrix} \cosh(\psi) & \sinh(\psi) \\ \sinh(\psi) & \cosh(\psi) \end{pmatrix} \quad (3)$$

where $\psi \equiv (\pi/\omega_e)(2\alpha_0)^{1/2}$. The axial (z) motion is stable if the two eigenvalues of the product of the matrices in equation (3) are complex. Thus, we have stability if $[\cosh(\psi) \cos(\psi)]^2 < 1$, or $\psi < 1.875$ or

$$\alpha_0 < 0.178 \omega_e^2 \quad (4)$$

This inequality implies stability in the transverse directions; that is, the rate of switching between the mirror and anti-mirror configurations must be rapid compared with the 'natural' frequency in the mirror field $(\alpha_0)^{1/2}$.

Equations (2) with $\alpha(t) = \alpha_0 \sin(\omega_e t)$ can be solved approximately in the limit where $\alpha_0 \ll \omega_e^2$ (ref. 24). Let $x = X + \xi$, where $X(t)$ is slowly varying on the timescale $1/\omega_e$, and $\xi(t)$ is rapidly varying. Notice that $X(t)$ is analogous to the guiding centre position of a charged particle in a magnetic field while ξ represents the rapid gyration. Then, $d^2\xi_x/dt^2 = -\alpha_0 \sin(\omega_e t) X_x$ or $\xi_x \approx (\alpha_0/\omega_e^2) \sin(\omega_e t) X_x$ and $d^2X_x/dt^2 \approx -\langle \alpha \xi_x \rangle \approx -(1/2)(\alpha_0/\omega_e^2) X_x$, where the angular brackets denote a time average over the interval $2\pi/\omega_e$. Similar formulae describe the y and z motion. Hence, the angular frequency for the slow motion is $\Omega_x = \alpha_0/(\omega_e\sqrt{2})$, $\Omega_y = \alpha_0/(\omega_e\sqrt{2})$, or $\Omega_z = \alpha_0\sqrt{2}/\omega_e$, for the x, y or z motion. For the guiding centre motion,

$$d^2X_j/dt^2 = -\partial V_e/\partial X_j$$

where

$$V_e(X) = \frac{1}{4} \left(\frac{\alpha_0}{\omega_e} \right)^2 (X_x^2 + X_y^2 + 4X_z^2) \quad (5)$$

is an effective potential, and $j = x, y$ or z . Note that the rapid motion ξ is out of phase with the mirror field $b(t)$: during the intervals in which the mirror field is attractive, $\alpha(t) > 0$ for, say, the x motion, the x displacement is $|X_x| + |\xi_x|$, which is larger than its value, $|X_x| - |\xi_x|$, during the intervals where $\alpha(t) < 0$. Hence, the attractive force exceeds the repulsive force. Note also that although $|\xi_j/X_j| \approx \alpha_0/\omega_e^2 \ll 1$, $|d\xi_j/dt|$ is not in general small compared with $|dX_j/dt|$.

Equations (2) and (5) can readily be generalized to account for the full spatial dependence²⁵ of the magnetic field $b_z(r, z)$ of one (or more) coaxial wire loops for $b_0^2 \ll B_0^2$. In place of equation (2), we write

$$\frac{d^2x_j}{dt^2} = \alpha(t) F_j(x) \quad (6)$$

for $j = x, y$ or z . Here, $\alpha(t) = \alpha_0 \sin(\omega_e t)$ with α_0 defined as before, below equation (2), and $F_j \equiv R^2 \nabla_j \{2b_z(r, z, t)/[3b_0(t)]\}$. An approximate solution is again obtained by letting $x = X + \xi$, where $d^2\xi_j/dt^2 = \alpha(t) F_j(X)$ or $\xi_j \approx -(\alpha/\omega_e^2) F_j(X)$. The slow, guiding centre motion obeys the equation

$$\frac{d^2X_j}{dt^2} = \sum_i [\partial F_j(X)/\partial X_i] \langle \alpha \xi_i \rangle = -\partial V_e/\partial X_j \quad (7)$$

where

$$V_e(X) = (1/4) (\alpha_0/\omega_e)^2 [F(X)]^2 \quad (8)$$

is the effective potential.

Figure 1 shows a contour plot of $V_e(r, z)$ obtained from equation (8) and the actual field $b_z(r, z)$ of a single circular coil of radius R . The lowest values of the effective potential are seen to occur along the z -axis, where the effective potential is

Fig. 1 Representations of the effective potential from equation (8) for the case where the b -field is caused by a single circular wire loop of unit radius in the x - y plane. *a*, An isometric view of the potential; *b*, the equipotentials. The two points denoted by V_m are separatrices. The trapped particles occupy the region $V_e \leq V_{\max} = 0.082 (\alpha_0/\omega_e)^2 R^2$. The equipotential contours are uniformly spaced with $\Delta V_e = V_{\max}/6$.

$V_e(0, z) = (\alpha_0/\omega_e)^2 z^2 [1 + (z/R)^2]^{-5}$. Thus, the 'top' of the effective potential, the separatrices of V_e , occur at $z = \pm R/2$ where $\max(V_e) \approx 0.0819 (\alpha_0 R/\omega_e)^2$.

Influence of collisions

Here, we consider the 'equilibrium' of a magnetically confined classical collisional gas in an oscillating mirror/anti-mirror field [$\alpha = \alpha_0 \sin(\omega_e t)$ in equation (6)]. Of course, the equilibrium will not be a simple Maxwell-Boltzmann distribution. For the present purposes the equilibrium can be described by the single particle distribution function (or phase space density) $f(x, v, t)$ which is a function of position x and velocity v , and which satisfies the Boltzmann equation

$$Df/Dt \equiv \partial f/\partial t + (v \cdot \nabla) f + (a \cdot \nabla_v) f = C(f, f) \quad (9)$$

where $C(f, f)$ is the Boltzmann collision integral, and $a_j = \alpha(t) F_j(x)$. A dimensionless measure of the 'strength' of the scattering is R/λ_0 . Here, $\lambda_0 \equiv [n(0)\sigma_{\text{tot}}]^{-1}$ is the mean-free path at the centre of the trap [at which point the number-density is $n(0)$], σ_{tot} is the total scattering cross-section, and R is the radius of the current loop (which is larger than the radius of the trapped gas). For the case of spin-polarized atomic hydrogen the scattering at low temperatures is predominantly the isotropic (S-wave) scattering of identical ('b' state) particles so that $\sigma_{\text{tot}} = 4\pi a_s^2$, where $a_s \approx 0.72 \times 10^{-8}$ cm (ref. 26). Thus, $\lambda_0 \approx 1.6$ cm [10^{15} cm⁻³/ $n(0)$].

Approximate solutions to equation (9) can be developed using the smallness of two parameters: $\varepsilon \equiv \alpha_0/\omega_e^2 \ll 1$ and $\delta \equiv \varepsilon R/\lambda_0 < 1$. We let $f = f_0 + f_1 + f_2 \dots$, where the zeroth approximation is

$$f_0(x, v, t) = K \exp(-H_0/T) \quad (10)$$

with

$$H_0(x, v, t) \equiv \frac{1}{2} [v - u(x, t)]^2 + V_e(x)$$

Fig. 2 Projections of the trajectory of a test particle for the conditions where $\hat{T} = 3 \times 10^{-3}$ and $\varepsilon = 0.076$. The \mathbf{b} field is due to a single circular loop. This trajectory corresponds to an elapsed time of $10^3 t_e$, where $t_e = 2\pi/\omega_e$. During this interval 490 collisions occurred. A Monte-Carlo method is used to include collisions in the orbit integrations. During each time step (dt) of the fourth-order Runge-Kutta orbit integration, a random background particle velocity \mathbf{v}_b is generated with v_b distributed according to equation (10). Whether or not a collision occurs is decided by a comparison of $(dt)n_b(\mathbf{x})\sigma_{\text{tot}}|\mathbf{v}_b - \mathbf{v}_t|$ with a Poisson-distributed random variable. If a collision occurs, the test particle velocity (\mathbf{v}_t) is modified by a rotation of $\mathbf{v}_b - \mathbf{v}_t$ in the centre of the mass frame to a randomly chosen direction. The code has been extensively tested by calculation of orbits in a time-independent potential with scattering off the corresponding Maxwell-Boltzmann background distribution $f_b(\mathbf{x}, \mathbf{v})$. The time-averaged position of the particle in phase space has been found to agree accurately with $f_b(\mathbf{x}, \mathbf{v})$, as it should.

Here, $K = \text{constant}$; $T = k_B T_0/m$, with T_0 the usual absolute temperature; V_e is given in equation (8); and $\mathbf{u} \approx d\mathbf{g}/dt$ is a time- and space-dependent flow-velocity with \mathbf{g} the above-mentioned rapid component of the single-particle motion. Specifically, we take $u_j = -(d\alpha/dt)F_j(\mathbf{x})/\omega_e^2$. Therefore, \mathbf{u} differs from $d\mathbf{g}/dt$ by a fractional amount of order ε ; and $\nabla \times \mathbf{u} = 0$ and $\nabla \cdot \mathbf{u} = 0$ in that F_j is proportional to $\nabla_j b_z$ and $\nabla^2 b_z = 0$. Thus, $\mathbf{v} = d\mathbf{X}/dt + \mathbf{u} + O(\varepsilon)$. Consequently, $H_0 = 1/2 (d\mathbf{X}/dt)^2 + V_e(\mathbf{X}) + O(\varepsilon)$ is an approximate constant of the single-particle motion. (We do not consider here the more general case where f_0 includes a dependence on the z component of the single-particle angular momentum.)

Because the collisions conserve energy and momentum, the functional form of f_0 gives $C(f_0, f_0) = 0$. This f_0 does not satisfy the Boltzmann equation (9) identically in that $Df_0/Dt = (df_0/dH_0)G$, where $G = \mathbf{v} \cdot \nabla(H_0)$. However, the time average (over intervals $2\pi/\omega_e$) of G or Df_0/Dt is zero. In order to account for the oscillating contribution from Df_0/Dt in equation (9), we let $f = f_0 + f_1$, where $Df_1/Dt = -Df_0/Dt$. Because $G = 0(\varepsilon\omega_e)$, we have $f_1 = O(\varepsilon)f_0$ with $\langle f_1 \rangle = 0$. Of course, with $f = f_0 + f_1$, the collision term in equation (9) takes on the non-zero value $C(f_0, f_1) + C(f_1, f_0)$. In order to account for this contribu-

Fig. 3 *a*, The time-averaged test particle density as a function of position through its dependence on $V_e(\mathbf{x}, y, z)$. The dependence for the background is $\exp(-V_e/T)$. *b*, The dependence on V_e of the ratio of the test particle temperature ($\langle v^2 \rangle/3$) to that of the background ($T + 2V_e/3$). The test particle quantities show good approximate agreement with the theoretical background distribution function (equation (10)).

tion in equation (9), we let $f = f_0 + f_1 + f_2$, where $Df_2/Dt = C(f_0, f_1) + C(f_1, f_0)$. From this equation, we estimate $f_2 = O(\varepsilon^2|x|/\lambda_0)f_0 < O(\varepsilon\delta)f_0 \ll f_0$.

We have numerically determined the orbits of test particles in an oscillating mirror/anti-mirror magnetic field including, via a Monte-Carlo method, collisions (S-wave scattering) of the test particle from the background distribution function given by equation (10). For a discussion of the numerical results it is convenient to use dimensionless variables: $\hat{x} \equiv x/R$, where R is a characteristic length; $\hat{t} \equiv t/t_e$, where $t_e \equiv 2\pi/\omega_e$; $\varepsilon \equiv \alpha_0/\omega_e^2$; $\hat{\lambda}_0 = \lambda_0/R$, where λ_0 is the mean free path at $x = 0$; $\hat{T} = (k_B T_0/m)(t_e/R)^2$ is the dimensionless temperature; and $\hat{V}_e = (t_e/R)^2 V_e$ is the dimensionless effective potential. Figure 2 shows two projections of the test particle trajectory for an illustrative case. Notice that the axial 'width' of the orbit is approximately one-half of the transverse (x or y) width. The approximate effective potential, equation (5), implies that $\langle z^2 \rangle = (1/2)(\omega_e/\alpha_0)^2 T$ and $\langle x^2 \rangle = \langle y^2 \rangle = 2(\omega_e/\alpha_0)^2 T$. Figure 3 shows the time-averaged density and temperature as a function of position [through $V_e(\mathbf{x}, y, z)$] implied by the test particle orbit for the same case as Fig. 2.

From a large number of Monte-Carlo orbit integrations, we find that test particles are confined (for intervals $> 10^3 t_e$) only within a restricted region of the (\hat{T}, ε) plane. The oscillating field \mathbf{b} is considered to be that of a single circular coil of radius R . The confinement region of the (\hat{T}, ε) plane is bounded from above the horizontal line $\varepsilon = \alpha_0/\omega_e^2 \approx 0.19$. Also, the confinement region is bounded from below by the diagonal line $\varepsilon \approx 1.27(\hat{T})^{1/2}$. This condition arises from the fact that the size of the trapped gas increases with T (for fixed α_0 , ω_e and R) so that at a large enough value of T the gas escapes readily. In terms of dimensionless variables, the above-mentioned maximum of the effective potential is $\max(\hat{V}_e) = 3.23 \varepsilon^2$. Thus, the diagonal line corresponds to $T/\max(V_e) \approx 0.19$.

In terms of the physical variables, the conditions for confinement can be expressed as

$$I < 1,400 \text{ A-turn} \left(\frac{R}{1 \text{ cm}} \right)^3 \left(\frac{f_e}{10^3 \text{ Hz}} \right)^2 \quad (11)$$

and

$$I > 2,700 \text{ A-turn} \left(\frac{T_0}{1 \text{ mK}} \right)^{1/2} \left(\frac{R}{1 \text{ cm}} \right)^2 \left(\frac{f_e}{10^3 \text{ Hz}} \right) \quad (12)$$

where I is the number of Ampere-turns of the circular coil and $f_e = \omega_e/2\pi$. For a gas of atoms of mass M different from that of atomic hydrogen, the right-hand sides of inequalities (11) and (12) are multiplied by M/m and $(M/m)^{1/2}$, respectively. In order for equations (11) and (12) to be compatible we need

$$f_e > 1.9 \text{ kHz} \left(\frac{T_0}{1 \text{ mK}} \right)^{1/2} \left(\frac{1 \text{ cm}}{R} \right) \quad (13)$$

Some illustrative values of the parameters are shown in Table 1b.

Evaporation and viscous heating

A small but finite rate of escape or evaporation of gas atoms from the magnetic trap is expected even when inequalities (11) and (12) are satisfied. We first consider the collisional limit where $\lambda_0 \ll R$ and where an approximate treatment can be made following Jean's theory of the escape of atoms or molecules from planetary atmospheres²⁷. Clearly, from Fig. 1, the 'easiest' route of escape is along the $\pm z$ directions. We let the effective potential maximum be $V_m = \max[V_e(0, z)]$ and z_m is the axial distance to the maximum. At a distance $z_c < z_m$ where the potential is $V_c = V_e(0, z_c)$, the gas effectively becomes collisionless. Out of a Maxwellian distribution of guiding centre velocities $[f(\mathbf{X}, \dot{\mathbf{X}})]$ of equation (10) at z_c , the atoms with outwardly directed velocities greater than the escape speed $[2(V_m - V_c)]^{1/2}$ exit from the trap. The rate of evaporation from the trap can be expressed as

$$\frac{dN}{dt} \sim -(\varepsilon\omega_e)\phi N \left(\frac{V_m}{T} \right) \exp\left(-\frac{V_m}{T}\right) \quad (14)$$

Here, N is the total number of atoms in the trap, and $\phi \sim 0.07$ is dimensionless. In the collisionless limit ($\lambda_0 \gg R$), we estimate $\phi \sim 0.8 N(\sigma_{\text{tot}}/R^2)(V_m/T)$. The crossover between the two limits is at $N \sim 0.1 (R^2/\sigma_{\text{tot}})(T/V_m)$ which is $\sim 2 \times 10^{13}$ for $T/V_m = 0.15$.

The rate of energy loss of the trapped atoms due to the evaporation can be estimated using the fact that most of the escaping particles only just get over V_m . This implies a total energy loss rate of $dE/dt = 3V_m(dN/dt)$. The factor of three accounts for the fact that an escaping atom takes with it both the potential energy of its slow motion, V_m , as well as the kinetic and potential energy of its fast, 'gyratory' motion, $1/2[u(0, z_m, t)]^2 + V_e(0, z_m) = 2V_m$. Of course, the total energy of the trapped gas can be written as $E = N(K + V)$, where $\langle K \rangle$ and $\langle V \rangle$ are the average particle kinetic and potential energies, respectively. The kinetic energy is the sum of a contribution due to the slow motion (K_s) and a contribution due to the gyratory motion (K_g) and similarly for the potential energy. Because of inequality (12), most of the atoms in the trap are near the bottom of the potential well which is quadratic. Therefore, we have $\langle K_s \rangle = 3T/2$, $\langle K_g \rangle = 3T/2$, $\langle V_s \rangle = 3T/2$ and $\langle V_g \rangle = 3T/2$ so that $E = 6NT$. If evaporation were the only process affecting the total energy of the trapped gas, we would have $d(NT)/dt = (1/2)V_m(dN/dt)$ or $N[(1/2)V_m - T] = \text{constant}$. Note that our inequality (12) corresponds to $T < 0.19 V_m$.

The 'equilibrium' distribution function (10) has the non-zero flow velocity $\mathbf{u}(\mathbf{x}, t)$. Therefore, there is in general an associated viscous dissipation of the flow energy into heat in the trapped gas. This heating, denoted $(dE/dt)_v$, reflects the fact that a dynamic magnetic trap is not a closed system; the oscillating magnetic field does work on the gas. Because $\nabla \times \mathbf{u} = 0$ and

$\nabla \cdot \mathbf{u} = 0$, we have

$$\left(\frac{dE}{dt} \right)_v = 2 \int d^3x n(\mathbf{x}) \nu(\mathbf{x}) \left\langle \left(\frac{\partial u_x}{\partial x} \right)^2 + \left(\frac{\partial u_y}{\partial y} \right)^2 + \left(\frac{\partial u_z}{\partial z} \right)^2 \right\rangle \quad (15)$$

(ref. 28). Here ν is the kinematic viscosity which may be estimated as $\nu \sim \langle (\Delta \mathbf{X})^2 \rangle / \tau$, where τ is the collision time, and $\Delta \mathbf{X}$ is the displacement of the guiding centre per collision²⁹. If $\tau \ll 2\pi/\omega_e$, the displacement per collision is of the order of the mean free path λ and the usual kinetic theory formula $\nu \sim \lambda^2/\tau$ holds. However, we expect to have $\tau > 2\pi/\omega_e$ or $\tau \gg 2\pi/\omega_e$ in most of the volume of the trapped gas. In this limit the displacement per collision is of the order of the 'gyro-radius' ξ so that $\nu \sim \langle \xi^2 \rangle / \tau$. Using this estimate, equation (15) can be integrated to give

$$\left(\frac{dE}{dt} \right)_v \sim \frac{18}{(2\pi)^{1/2}} \left(\frac{T^{1/2}}{\lambda_0} \right) \varepsilon^2 NT \quad (16)$$

Here, $\lambda_0 = [n(0)\sigma_{\text{tot}}]^{-1}$, so that $\lambda_0/T^{1/2}$ is roughly the collision time at the centre of the trap. Equation (16) is in approximate agreement with the heating seen in our Monte-Carlo orbit calculations.

The combined classical influences of viscous heating and evaporative cooling are described approximately by the equations

$$\frac{dT}{dt} \sim (\varepsilon\omega_e) V_m [g\varepsilon^2(\sigma_{\text{tot}}/R^2)N - \phi(\frac{1}{2} - T')F(T')] \quad (17)$$

$$\frac{dN}{dt} \sim -(\varepsilon\omega_e)\phi NF(T') \quad (18)$$

which follow from equations (14) and (16). Here, $T' \equiv T/V_m$; $F \equiv (T')^{-1} \exp(-1/T')$ and $g \equiv 0.082(\alpha_0 R/\omega_e)^2/V_m$ with $g = 1$ for the case of a circular wire loop of radius R . If ε and ω_e are assumed to be constant, then from a high initial temperature, the trapped gas first moves comparatively rapidly towards the (T, N) curve along which $dT/dt \approx 0$. Along this curve, $|dT/dt|$ is small compared with the magnitude of the separate terms on the right-hand side of equation (17) which corresponds to an approximate balance of the viscous heating and evaporative cooling. Subsequently, the gas moves slowly down the $dT/dt \approx 0$ curve with the number of gas atoms decreasing gradually. The curve $a-c$ in Fig. 4 shows a typical cooling track. The viscous heating prevents the trapped gas from freely evolving into the region where Bose-Einstein condensation is expected to occur.

A possible strategy for reaching the Bose-Einstein region in Fig. 4 is as follows. We first alternate between cooling and filling the trap. Assume that there are initially a small number of atoms, N_i , in the trap at a 'high' temperature, T_i , so that the viscous dissipation is negligible. The starting conditions may be considered to be the point denoted by a in Fig. 4. After a short interval, the evaporative cooling brings the gas to point b , where the temperature is $\beta T_i < T_i$ and the density is $N = \gamma N_i$, where $\gamma \approx (1 - \tau_i)/(1 - \beta\tau_i) < 1$, with $\tau_i \equiv 2T_i/(V_m)$. The fact that the temperature is reduced facilitates the addition of gas to the trap. This addition may be accomplished by rapidly injecting a tight clump of atoms while the effective potential barrier V_m is momentarily reduced. A sequence of cooling and filling cycles is shown in Fig. 4.

After a sufficiently large value of N is achieved (point f in Fig. 4), it becomes advantageous to do the evaporative cooling with the mirror field strength ε slowly decreasing with time, which has the effect of lowering the walls of the trap. This value of N is below the $dT/dt \approx 0$ curve so that viscous heating is negligible initially and its relative importance diminishes with time. In this case, the $dT/dt \approx 0$ curve in the (T, N) plane moves upward and leftward as T decreases. Because the spring constant of the effective potential well ε^2 is decreasing with time, we must include a term $+(T/\varepsilon)(d\varepsilon/dt)$ on the right-hand side of equation (17) to account for the decrease of T due to adiabatic expansion. (In the absence of evaporation T would be proportional to ε .) For specificity, consider programming $\varepsilon(t)$ to

Fig. 4 Evolutionary tracks for the total number of trapped gas atoms (N) and the gas temperature (T) from equations (17) and (18) which describe the combined influences of evaporative cooling and particle loss, and of viscous heating. Except for the line f - g , the parameters are: $\epsilon = 0.06$, $T_i/V_m = 0.15$, $T_i = 1$ mK, $R = 1$ cm and $f_e = 6.9$ kHz, which are appropriate for the case where the b -field is due to a single circular loop of radius R . Along the line f - g , $\epsilon = 0.06 (T/T_i)^{1/2}$. The curve denoted $dT/dt \approx 0$ corresponds to an approximate balance of the evaporative cooling and the viscous heating. Note that equations (5) and (10) imply $n(0) \approx 1.9 (N/R^3) (V_m/T)^{3/2}$, which is $\approx 32(N/R^3)$ for $T/V_m = 0.15$. The solid straight diagonal line corresponds to $N \approx 1.7[k_B T_0/(\epsilon \hbar \omega_c)]^3$ with $\epsilon = 0.06$, which is the condition for Bose-Einstein condensation in the static potential given by equation (5). This condition for condensation can be rewritten in terms of $n(0)$ and T so that it is similar to the formula given in the introduction. The dashed straight line is the same condition for Bose-Einstein condensation but with $\epsilon = 0.06(T/T_i)^{1/2}$.

decrease in such a way that $T' = T/V_m = \text{constant}$. Because V_m is proportional to ϵ^2 we have $\epsilon = \epsilon_i (T/T_i)^{1/2}$, where i indicates the value at point f . From inequality (11), we must have $\epsilon_i < 0.19$. Equations (17) and (18) now imply

$$NT^{-\delta} = \text{constant} \quad (19)$$

where $\delta \equiv (\frac{1}{2})T'(\frac{1}{2} - T')^{-1}$. From inequality (11), we must have $T' < 0.19$. For $T' = 0.1, 0.15$ and 0.19 we have $\delta \approx 0.125, 0.21$ and 0.31 , respectively. The line f - g in Fig. 4 shows the evolutionary track. This track takes the gas into the region of Bose-Einstein condensation. Of course, in this region equations (17) and (18) must be modified to account for quantum mechanical effects²⁰, including, in particular, the fact that a non-negligible fraction of the trapped atoms may be in the condensate. Note that the timescale for the evolution from points a to g in Fig. 4 is quite rapid (~ 1 s). Once point g is reached, ϵ may be fixed. The evolution is then essentially frozen at point g .

Conclusions

Much effort will be needed to attain conditions for Bose-Einstein condensation of atomic hydrogen gas in a dynamic trap. The trapping region would need to be inside a thin non-conducting cylindrical wall with the coil windings for the b field located outside this wall in a large bath of liquid helium. For a coil of inner radius ~ 1 cm and, say, 2×10^3 turns, the inductance is ~ 20 mH and the currents needed are ≤ 10 A. The inductive impedance of the coil can be cancelled at the frequency f_e by an appropriate series capacitor. An estimation of the circuit resistance at resonance for copper wire gives a value $\sim 0.5 \Omega$. Thus, during the initial rapid evolution of the gas from points a to g in Fig. 4, the ohmic losses in the coil will be ≤ 25 W

during an interval ~ 1 s. Subsequently, at point g the ohmic losses will be a factor ≥ 10 smaller. The heat from the coil will go into boiling off a fraction of the helium from the bath.

A major problem will be that of supplying a sufficiently large number of low-temperature hydrogen atoms to fill the trap. The walls of the tube carrying the hydrogen atoms to the trap will be coated with a superfluid film of helium. Because the binding energy of a hydrogen atom to such a film is of the order of 1 K, the atoms will have a strong tendency to adhere to the walls for temperatures below 0.1 K. On the other hand, it is desirable to fill the trap with gas at a temperature below 0.01 K to avoid the need for even larger oscillating magnetic fields. However, it is not known how much below 0.1 K the hydrogen gas can be cooled by wall collisions. The accommodation coefficient is predicted to decrease monotonically with decreasing temperature³⁰, which means that the thermal disequilibrium between the wall and the gas becomes larger at lower wall temperatures when one is attempting to cool a 'hot' beam of atoms with wall collisions. An alternative approach may be to rely on hydrogen atom surface transport via diffusion along the helium film surface to the trap region (J. D. Reppy, personal communication). It may be possible to detach the hydrogen atoms from the film surface in the trap region using carefully controlled thermal³¹, sonic or magnetic gradient pulses. Another approach might involve forming a collimated and velocity-selected atomic beam which is then slowed down by a magnetic field gradient.

Another important challenge will be the detection of the Bose-Einstein condensation. Sensitive techniques are available for detecting hydrogen atoms using nuclear magnetic resonance (where 10^{14} atoms can easily be detected)³² and electron spin resonance (where 10^9 atoms can be detected)^{33,34}. In the potential well provided by the trap, the condensed hydrogen atoms (which are bosons) will tend to congregate in the low-energy states of the well (energies $\ll k_B T$), which are relatively compact in configuration space^{20,35-37}. A clear manifestation of Bose-Einstein condensation would be the appearance of a spatially compressed (condensate) component of the trapped gas. This compressed component should be evident in magnetic resonance imaging experiments. Another remarkable prediction¹⁸ is that of the appearance and precession of a spontaneous magnetization of the condensate of a hydrogen gas made up of both 'a' and 'b' states. It seems reasonable to expect that various new quantum phenomena will be found in Bose-Einstein condensed atomic hydrogen gas.

An inherited limb deformity created by insertional mutagenesis in a transgenic mouse

We have created an insertional mutation that leads to a severe defect in the pattern of limb formation in the developing mouse. The novel recessive mutation is phenotypically identical and non-complementary to two previously encountered limb deformity mutations, and is closely linked to a dominant mutation that gives rise to a related limb dysmorphism. The inserted element thus provides a molecular genetic link with the control of pattern formation in the mammalian embryo.

THE molecular events that guide pattern formation during embryonic development have been difficult to characterize in mammals, partly because of the difficulty in drawing a molecular connection between the phenotype of a dysmorphic mutation and the specific gene in which that mutation occurs. One means of overcoming this problem involves creating developmental mutants by insertional mutagenesis in transgenic mice and using the inserted DNA fragments as markers to clone the mutant genes. Initially, one might expect such mutants to be prohibitively rare, but, using a related approach, Jaenisch and colleagues^{1,2} have identified an embryonic lethal mutant as an insertional mutation in the $\alpha 1(I)$ collagen gene. Additional potentially interesting mutants in transgenic mice have been identified by others^{3,4}.

Recently, we created several strains of transgenic mice for experiments designed to understand the action of the oncogene *c-myc*⁵. To test for gene dosage effects, these strains were bred to homozygosity with respect to the inserted gene (in this case, a fusion construct of the mouse mammary tumour virus long terminal repeat and the mouse *c-myc* gene; MMTV-*myc*). We also systematically screened these animals for recessive lethal or dysmorphic mutations. Among seven transgenic mouse strains analysed in this way, we discovered one carrying a recessive mutation that results in a severe dysmorphism of all four limbs.

Discovery of limb deformity mutation

In preparing transgenic mice, the DNA fragments which are injected into the fertilized egg integrate into the host genome, usually at a single site, and become a stably heritable genetic element⁶⁻¹¹. From the analyses that have been done so far, no clear rules have emerged regarding the site of integration. It is, therefore, conceivable that these DNA fragments will occasionally integrate within or near, and hence disrupt the function of, a gene whose expression is essential for the normal development of the animal. For this and other reasons related to our original experimental purposes, we systematically intercrossed transgenic heterozygous animals. In this manner, the phenotype of any recessive mutation caused by the inserted MMTV-*myc*

sequences would become apparent on examination of the homozygous offspring.

In one of these lines of transgenic mice, designated the S line (previously called 165-1a)⁵, some of the offspring from heterozygous parents were abnormal. The fore- and hindlimbs of these animals were deformed, and some of the digits in their fore and hind paws appeared to be fused (Fig. 1A). We analysed the skeletons of several affected animals and noted that in all cases there was a synostosis of the long bones (radius-ulna/tibia-fibula), oligodactyly (absence of post-axial digits), fusion of some carpals, tarsals, metacarpals and metatarsals, and syndactyly (Fig. 1B). The axial skeleton appeared normal. To enhance their chances of survival, the affected animals usually had to be removed from the competition of their wild-type littermates during nursing. As adults, at least some of the affected animals have proven to be fertile.

Co-segregation

To investigate whether the mutation causing the limb deformity in these transgenic animals co-segregated with the MMTV-*myc* integration site, several mice known to be heterozygous for the limb deformity were mated either with each other or with homozygous wild-type littermates (Table 1). The latter matings

Table 1 Limb deformity phenotype segregates as a recessive trait

† Present addresses: Central Research and Development Department, Experimental Station, E. I. DuPont de Nemours & Co., Inc., Wilmington, Delaware 19898, USA (L.G.D.); Genentech, 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA (T.A.S.).

Fig. 1 Characteristics of the limb deformity phenotype. The figure shows a mouse expressing the limb deformity defect compared with a normal littermate. **A**, Two 4-day-old animals from the offspring of a mating between heterozygous parents. The lower animal expressed the mutant phenotype; arrows indicate the defective fore- and hindlimbs. **B**, Skeletal structures of the homozygous mutant (on the left) and the wild-type mouse. The abnormal regions of the mutant skeleton are indicated by arrows: *a*, synostosis of the radius and ulna; *b*, oligodactyly and syndactyly of the digits of the fore paw, as well as fusion of some carpals and metacarpals; *c*, synostosis of the tibia and fibula; *d*, oligodactyly and syndactyly of the digits in the hind paw, as well as fusion of some tarsals and metatarsals.

Methods. To visualize the skeleton of the animals, the staining procedure described by McLeod²⁴ was used. Briefly, the animals were eviscerated and their pelage was removed. The samples were then placed in 95% ethanol for 7 days, followed by 24 h in acetone. The bones were stained red and the cartilage stained blue in a solution containing Alizarin red (Sigma) and Alcian blue (Sigma). The soft tissue was then cleared in a 1% KOH solution to allow the bone and cartilage to be visualized.

(heterozygote \times homozygous wild type) yielded no animals with the limb deformity among 57 offspring from 10 litters. Similarly, matings between homozygous affected and wild-type littermates yielded no affected offspring. The cross between heterozygous individuals, however, yielded 21% deformed animals among 186 offspring from 22 litters. These results are consistent with an autosomal recessive mode of inheritance at a single locus (39 affected individuals among 186 informative offspring: 46.5 were expected to be affected, $\chi^2_1 = 1.612$; $0.10 < P < 0.25$). To test the possibility that the limb abnormality was co-segregating with the MMTV-*myc* sequences, genomic DNAs from the tails of individuals from three representative litters were analysed to determine their genotypes (using the restriction fragment length polymorphism (RFLP) analysis described in Fig. 3 legend) (see Fig. 2). Only individuals homozygous for MMTV-*myc* sequences expressed the limb abnormality; MMTV-*myc* heterozygotes and animals entirely lacking these sequences were phenotypi-

cally normal. The recessive limb deformity thus appears to segregate with the site at which the MMTV-*myc* sequences integrated. Hereafter, *ld^{ld}* will be used to refer to this mutant locus.

Cloning of mouse genomic DNA

As the MMTV-*myc* sequences segregated with the limb abnormality, the mutation giving rise to the defect may have been caused by the integration of the foreign DNA sequences. While the disorder might be the result of expression of an inserted gene, it is more likely (see below) that the MMTV-*myc* sequences integrated into, and hence disrupted the function of, a cellular gene that participates in the development of the fore- and hindlimbs during embryogenesis. To evaluate this possibility, we cloned the mouse genomic DNA flanking both sides of the inserted MMTV-*myc* sequences in the genome of the transgenic animal.

Fig. 2 A representative pedigree showing offspring of heterozygous parent mice from the S transgenic line. The offspring (II-1 to II-24) of two different females (I-1 and I-3) and two different males (I-2 and I-4) are shown. The offspring numbered II-1 to II-16 represent a combined litter of animals from the mating of the I-1 and I-3 females with the I-2 male. All four parents were phenotypically normal; the phenotype of the individual animals is indicated by WT for wild type and *ld* for limb deformity. Males are represented by squares, and females by circles. Individuals that do not contain the MMTV-*myc* sequences are indicated by open circles or squares. Half-filled circles or squares represent transgenic heterozygotes, while completely filled circles or squares represent homozygous transgenic animals. Heterozygosity was distinguished from homozygosity using the RFLP method indicated in Fig. 3 legend. \diamond , The animal died before its sex could be determined. A slash through a symbol indicates that the animal died before its genotype could be established.

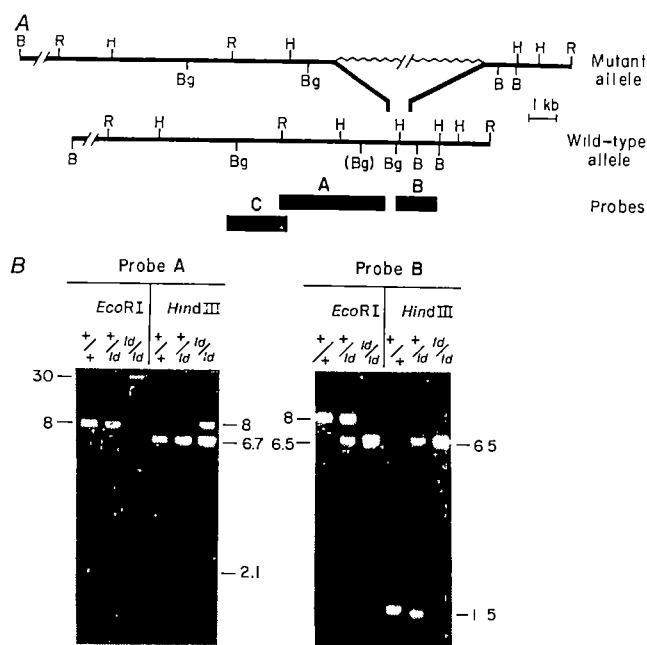

Fig. 3 Characterization of the region of the mouse genome interrupted by the inserted MMTV-*myc* sequences. **A**, Structure of a region of the mutant mouse allele containing the inserted MMTV-*myc* sequences (indicated by a wavy line) and its corresponding normal allele. The sequence between the bold lines which extends down from the mutant allele to specific sites on the normal allele is deleted in the mutant allele. Three different DNA fragments (A, B and C), represented by solid boxes, were nick-translated and used as probes in the present study. Restriction enzyme sites: H, *Hind*III; R, *Eco*RI; B, *Bam*HI; Bg, *Bgl*II. (The *Bgl*II site in parentheses is a polymorphic site and is present in only some of the alleles at this locus.) **B**, Southern blot of *Eco*RI- or *Hind*III-digested genomic DNA from an outbred CD1 mouse (+/+) or from heterozygote (*ld*/+) or homozygote (*ld*/*ld*) transgenic mice. (In this figure *ld* refers to the *ld*^{Hd} mutation.) The samples were hybridized with the nick-translated restriction fragments indicated as probes A and B in **A**. Numbers refer to the size (in kb) of the hybridizing fragments.

Methods. A portion of the mutant allele was initially cloned by preparing a genomic cosmid library with size-fractionated (30–40 kb), partial *Sau*3A-digested genomic DNA fragments from the liver of an animal of the S transgenic line. These fragments were ligated into a cosmid vector with an inactivated ampicillin resistance (*Amp*^r) gene. The cosmid vector that we used for this purpose was derived from the c2RB vector constructed by Bates and Swift²⁵ which contains both *Amp*^r and kanamycin resistance (*Kan*^r) genes. The *Amp*^r gene in the c2RB vector was inactivated by digestion at the unique *Pvu*I site in its *Amp*^r gene, filling-in the overhanging single-stranded ends with T4 DNA polymerase, and then blunt-end ligating the molecule with T4 DNA ligase. The *Kan*^r gene between the *cos* sites facilitated the growth of the modified vector in *Escherichia coli*. Cosmids which grew on ampicillin plates had acquired an *Amp*^r gene from the pBR322 sequence in the transgenic mouse DNA. (These pBR322 molecules were injected together with the MMTV-*myc* sequences in the preparation of the S line transgenic mice.) One such cosmid contained an insert comprised of a segment of MMTV-*myc* sequence together with 9 kb of mouse genomic sequence. The wild-type allele was cloned by screening a normal mouse library²⁶ which we prepared using the unmodified c2RB vector and a probe derived from the 9 kb of mouse genomic sequence that was cloned with the *Amp*^r-defective vector. Only a portion of the cloned sequences is shown in the figure.

We initially cloned 9 kilobases (kb) of mouse genomic DNA from the region flanking one side of the MMTV-*myc* sequence using a cosmid vector that was specifically modified for this experiment. This vector allowed us to select for the β -lactamase activity on the pBR322 sequences that were interspersed with the MMTV-*myc* sequences in the genomic DNA of the transgenic animal (see Fig. 3 legend for details). A region of this cloned 9-kb sequence was then used as a probe to isolate the

Fig. 4 The MMTV-*myc* integration site lies on chromosome 2. Using the Southern blot technique²⁷, we analysed wild-type BALB/c mouse and E36 hamster DNA samples, as well as DNA extracted from the 2A2B1, 2A2C2, 2A2H3 (ref. 22) and ABm5 and ABm14 (ref. 23) mouse-hamster somatic cell hybrids. A detailed chromosomal analysis of these somatic cell hybrids is given in Table 2. Genomic DNA (20 μ g) was digested with *Hind*III, electrophoresed through a 0.8% agarose gel, then transferred to nitrocellulose²⁷. A nick-translated restriction fragment, designated probe C in Fig. 3, was used as a probe for this experiment. The numbers refer to the size of the mouse and hamster hybridizing fragments. The presence or absence of mouse chromosome 2 in the individual samples of DNA is indicated by a + or -.

uninterrupted copy of this locus from a cosmid library constructed with DNA from a wild-type mouse. Using these clones, the structure of the locus into which the MMTV-*myc* sequences integrated was deduced (Fig. 3A).

To determine the structure of the interrupted mutant allele, genomic DNAs from a wild-type mouse (+/+) and from transgenic mice containing either one copy (*ld*^{Hd}/+) or two copies (*ld*^{Hd}/*ld*^{Hd}) of the interrupted allele were digested with *Eco*RI or *Hind*III and hybridized with sequences from either side of the insertion site (probes A and B in Fig. 3A). Both probes hybridized to the 8-kb *Eco*RI fragment that spans the insertion site in the wild-type allele (see Fig. 3B). In contrast, probe A hybridized to a 30-kb fragment and probe B hybridized to a 6.5-kb fragment in the mutant allele. The size-altered hybridizing fragments from the mutant allele probably represent the junction restriction fragments that contain a portion of the inserted MMTV-*myc* sequences. With the *Hind*III-digested DNA, probe A hybridized to 2.1-kb and 6.7-kb fragments on the wild-type sample; an 8-kb fragment was observed instead of the 2.1-kb fragment in the mutant allele. Using probe B and *Hind*III-digested DNA, a 1.5-kb hybridizing fragment (corresponding to the restriction fragment used as a probe for this analysis) was observed with the wild-type DNA; this fragment was replaced by a 6.5-kb fragment in the mutant allele. Based on these results, as well as other data including similar analyses with several other restriction enzymes (data not shown), it appears that a small region of ~1 kb has been deleted from the mouse genome as a consequence of the integration of the MMTV-*myc* sequences. Aside from this deletion, no other gross rearrangement within several kilobases of the integration site has been detected (data not shown).

Chromosomal mapping of integration site

Several morphogenetic loci that affect the development of the fore- and hindlimbs of the mouse have been identified¹². To determine whether the site of insertion of the MMTV-*myc* sequences correlates with the position of any of these loci, we chromosomally mapped the insertion segment. For this purpose, we hybridized genomic DNA from several mouse-hamster somatic cell hybrids with a probe derived from a region near the site of integration (Fig. 4). Based on the results of this

Fig. 5 Pedigree showing the 19 offspring of the mating of heterozygous parents containing the ld^{Hd} , ld^J or ld^{OR} limb deformity alleles. The phenotypes of the parents and offspring are indicated: WT, wild-type; ld , limb deformity. Symbols are as described for Fig. 2, except that \square , \circ , \otimes and \boxtimes indicate that the animal was a heterozygote. Circles or squares which are both half-solid and half-stippled refer to those animals that had inherited two defective copies of the limb deformity allele, one from each parent. **A**, Analysis of the nine offspring (1-9) from a single mating between a heterozygous S line transgenic ($ld^{Hd}/+$) mother and a Jackson ($ld^J/+$) father. The wild-type allele migrates as a 15-kb fragment, while the mutant transgenic and Jackson alleles migrate as 13- and 18-kb fragments, respectively. **B**, Analysis of the 10 offspring (10-19) from a single mating between a heterozygous S transgenic ($ld^{Hd}/+$) mother and an Oak Ridge ($ld^{OR}/+$) father. The wild-type allele migrates as a 5.5-kb fragment, while the ld^{Hd} and ld^{OR} alleles migrate as 2.8- and 0.8-kb fragments, respectively. (The 4.5-kb fragment is present on both the ld^{Hd} and ld^{OR} alleles, but not on the wild-type allele; this is due to the presence of the polymorphic *Bgl*III site (shown in parentheses in Fig. 3A) in both mutant alleles). In each case 10 μ g of genomic DNA from the parents or from their individual offspring were digested with *Bam*HI (**A**) or *Bgl*III (**B**), electrophoresed on a 0.8% agarose gel, transferred to nitrocellulose²⁷, then hybridized with a nick-translated restriction fragment (probe A in Fig. 3).

analysis, we have assigned the insertion site to chromosome 2, distal to band C1. The murine 6.7-kb hybridizing fragment was detected only in those somatic cell hybrids containing chromosome 2 or a derivative of chromosome 2 distal to band C1 (Table 2, Fig. 4). The hamster DNA yielded a 4-kb hybridizing band of moderate intensity, even under the high-stringency washing conditions used in the analysis ($0.2 \times \text{SSC}$, 0.1% SDS, 65°C); this fragment in the hamster genome must contain a region that is highly homologous with a section of the mouse restriction fragment used here as a probe.

Complementation tests

Examination of the genetic map of mouse chromosome 2 revealed the presence of several mutations which affect the development of the fore- and hindlimbs¹³. In particular, one mutation (designated ld for limb deformity) was reported to have an inheritance pattern and mutant phenotype strikingly similar to those of our transgenic mice. As we had observed with our mutant mice, in animals expressing this ld mutation the tibia and fibula were replaced by a single bone, the radius

and ulna were fused, and the bones in the fore and hind paws were reduced¹⁴⁻¹⁶. Two alleles of this mutation have thus far been observed: one at Jackson Laboratories (designated here as ld^J) and the other, possibly radiation-induced, at Oak Ridge National Laboratories (designated here as ld^{OR}). Both these mutations have been preserved by over 20 years of continuous passage.

To test for complementation between the ld^{Hd} mutation in our transgenic mice and the ld^J and ld^{OR} mutations, female transgenic heterozygotes ($ld^{Hd}/+$) were mated with heterozygous male animals from either the Jackson ($ld^J/+$) or Oak Ridge ($ld^{OR}/+$) laboratories (Fig. 5). As all three limb deformity mutations are recessive, offspring expressing the characteristic limb deformity should occur only if the mutations occur in the same complementation group. Examination of the offspring from these matings revealed several individuals expressing a limb defect that was identical to that which we observed in the transgenic mice (Fig. 5). This finding suggested that the ld^{Hd} mutation might be allelic to the ld^J and ld^{OR} mutations.

To investigate this point further, we identified RFLPs that

† Abm5 contains only a deletion derivative chromosome 2, $\text{del}2(\text{C1} \rightarrow \text{ter})$ ²³.

segregated with the ld^J and ld^{OR} mutations. As shown in Fig. 5A, the ld^J mutation segregated with an 18-kb *Bam*HI fragment that could be distinguished from both the 13-kb fragment that segregated with the ld^{Hd} mutation and the 15-kb wild-type fragment. In addition, the ld^{OR} mutation segregated with a 0.8-kb *Bgl*II fragment, which differs in size from the 2.8-kb and 5.5-kb *Bgl*II fragments that segregated with the ld^{Hd} and wild-type genes, respectively (Fig. 5B). (With the probe used for this experiment, the 4.5-kb *Bgl*II fragment shown in Fig. 5B is common to both the ld^{OR} and ld^{Hd} mutants.) These polymorphisms allowed us to establish the ld genotype of the offspring from the matings described above (Fig. 5A, B).

A comparison of the genotype of the individual animals with their corresponding phenotype revealed that animals that inherited two copies of the wild-type RFLP or only one copy of a mutant-linked RFLP were phenotypically normal. On the other hand, those animals that inherited a mutant-linked RFLP from both parents displayed the mutant phenotype. Therefore, the mutation reported for our transgenic animals is probably allelic to the ld^J and ld^{OR} mutations.

Development of the phenotype

There are two arguments that mitigate against a direct role for the *c-myc* gene product in the development of the ld phenotype. The more compelling argument follows from the occurrence of the two previously characterized mutations that give rise to the ld phenotype. As neither mutation involves an aberrant *c-myc* at the ld locus, it is clear that the phenotype can arise independently of an aberrantly expressed *c-myc* gene. In addition, expression of the inserted *c-myc* fusion gene occurs in the mammary gland and other tissues of heterozygotic S line transgenic mice (ref. 5 and data not shown). Assuming that there are no gene dosage effects, one would expect the mutation to be dominant if expression of the MMTV-*myc* gene is involved in the development of the ld phenotype. Indeed, the inserted fusion gene does behave as an autosomal dominant mutation with respect to the development of breast adenocarcinomas in S strain females (data not shown). Therefore, the autosomal recessive behaviour of the mutations is most easily reconciled with loss of function of the ld gene.

Role of ld gene product

One model of ld gene action holds that the normal homologue of the gene is temporally regulated during development and is expressed within the cells comprising the developing limb bud. In the mouse, the forelimbs develop first and appear as outgrowths of tissue along the side of the developing 10-day embryo¹⁷. During the next few days, the limb buds undergo extensive proximal-distal elongation, a process that may be under the control of the apical ectodermal ridge at the distal rim of the limb bud¹⁸. It has been speculated that control of

anterior-posterior pattern formation in the limb bud (the axis affected by the ld mutation) is governed by a morphogen gradient produced by the cells in a region called the zone of polarizing activity¹⁹. As the postulated gradient produced by this zone could affect the normal development of the radius, ulna and digits²⁰, the limb deformity mutation might disrupt the function of a gene normally expressed in this zone. On the other hand, expression of the gene at the ld locus could also occur in the mesenchymal cells that ultimately condense to form the bony structures within the limb. For example, the product of the ld gene could be a growth factor, a growth factor receptor or a specific cell-surface identity marker. Hopefully, additional experiments using cloned fragments from the ld locus will allow us to identify the site(s) of synthesis and action of the ld gene product.

Potential relationship to *lst* mutation

Another limb bud mutation has been mapped within two centimorgans of the ld mutation on chromosome 2 of the mouse. The mutation, Strong's luxoid (*lst*), exhibits genetic and phenotypic behaviour that is opposite from that of ld ²¹: instead of being recessive, it is dominant and instead of giving rise to too few bones in all four limbs, it gives rise to too many, that is, it is characterized by, among other things, polydactyly and duplications of the radius and tibia. As ld and *lst* were both mapped with respect to external markers and were not tested for allelism (P. Lane, personal communication), it is possible that these mutations lie much closer to one another than is suggested by the resolution of the current mapping data. We propose a very simple model that accounts for each of the mutations by allowing them to occur in the same locus. Thus, ld could represent a class of recessive mutations resulting in loss of gene function, for example by alteration of a coding sequence or promoter site, while *lst*, with its dominant behaviour, could act as a regulatory mutation in the same gene, for example by increasing the level of the ld product or allowing it to be expressed inappropriately. Fortunately, *lst* has also been preserved for the past 30 years, most recently as a frozen embryo, and will soon be available to test this possibility.

We thank Priscilla W. Lane of the Jackson Laboratories and Savanna Maddux of the Oak Ridge National Laboratories for their help in locating the extant ld mutations; Sidney Beck for help in preparing the photographs of the mice; and Lewis Holmes for advice and discussions. We also acknowledge the assistance of Terri Broderick in the preparation of this manuscript. Portions of this work were supported by grants from the E. I. DuPont de Nemours & Co., Inc., the American Business for Cancer Research Foundation and a Leukemia Society of America Scholar Award and Basil O'Connor Award (National Foundation/March of Dimes) to P.D'E. R.P.W. was supported by a fellowship from the Jane Coffin Childs Memorial Fund.

Randomness in quantum mechanics—nature's ultimate cryptogram?

T. Erber*

Department of Physics, University of California, Los Angeles, California 90024, USA

S. Putterman*

Department of Applied Mathematics, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, UK

Will a single atom irradiated by coherent light be equivalent to an infinite computer as regards its ability to generate random numbers? As described here, a search for unexpected patterns of order by cryptanalysis of the telegraph signal generated by the on/off time of the atom's fluorescence will provide new experimental tests of the fundamental principles of the quantum theory.

Dehmelt's pioneering work on the storage of single electrons and ions in macroscopic potential wells is currently being extended to neutral atoms and more complicated trapping schemes^{1,2}. These systems are interesting not only because they permit extremely accurate measurements of frequencies, or energies, but also because they are potentially useful in exploring new quantum effects. One possibility is the observation of individual quantum jumps by means of optical double-resonance methods^{1,3}. The novel aspects of this arrangement are that the fluorescent decays of a single atom can be observed, and further that the system can be reset by coherent excitation. The time delays between the resets and decays form a nominally 'random' binary telegraph signal. If the jumps are inherently indeterminate, arbitrarily long strings of random numbers can be generated by these signals⁴. In this respect quantum mechanics implies that even the simplest physical systems are equivalent to algorithms and computers of unbounded complexity⁵. This idea can be checked by searching for latent patterns of order in the sequence of fluorescent decay times. Powerful new theorems on the orbit structures of pseudo-random functions can aid in the cryptanalysis of these telegraph signals⁶. Externally induced correlations can also be exploited for precision field measurements.

The essential components of Dehmelt's shelved electron scheme for generating random fluorescence signals are shown in Fig. 1. A single atom or ion is stored in a macroscopic potential well. The present state of this technique is illustrated by the fact that a single Ba^+ ion can be localized to within $0.2\ \mu\text{m}$, or $2,000\ \text{\AA}$, in a radio frequency quadrupole trap with an effective well depth of $10\ \text{V}$; with a vacuum of 10^{-11} torr, or a residual gas density of 10^5 molecules cm^{-3} , the ion can be cooled to an equivalent temperature of $10\ \text{mK}$ and stored for hours^{1,7}. If the trapped object has an energy level structure of the type indicated in Fig. 1, a random telegraph signal can be generated by double-resonance methods³. Specifically, let us suppose that the ground state O and the excited level S are connected by a strong optical transition—that is, the matrix element $\langle O | e^{-i\mathbf{k}\cdot\mathbf{r}} | S \rangle$ is large. Then incident light (with wave vector \mathbf{k}) at frequencies matching ω_{strong} will induce transitions of an atomic electron between O and S at the Rabi flopping frequency. All the downward transitions $S \rightarrow O$ are accompanied by photon emission. A fraction of these re-radiated induced will be coherent with the incident light in virtue of emission or coherent Compton scattering. These coherent photons will be mixed with the transmitted beam. Experimentally it is much easier to detect the incoherent or fluorescent photons that are emitted transversely to the incident beam. In particular, if the strong transition $O \rightleftharpoons S$ is saturated

Fig. 1 Double-resonance method for generating a nominally random telegraph signal. During the time that an atomic electron is 'shelved' in state W , the fluorescence signal emanating from the $O \rightleftharpoons S$ transitions is quenched.

by the incident light, the fluorescent emission can be of the order of 10^8 photons s^{-1} , and this luminosity is sufficient to make the single trapped object visible through a microscope^{1,7}.

Suppose now, as shown in Fig. 1, that the ground state O is also weakly coupled to another excited level W . If the trapped object is simultaneously illuminated by two beams, one tuned to ω_{strong} and the other to ω_{weak} , the electron will continue to make many rapid transitions between O and S , but occasionally the incident ω_{weak} -beam will excite the upward transition $O \rightarrow W$. Clearly, while the electron is 'shelved' in state W , the fluorescence signal associated with the strong transition $S \rightarrow O$ will be shut off. However, when the electron returns to the ground state O via a spontaneous or induced decay, the strong fluorescence will switch on again. In this sense the fluorescence emanating from the strong transition is a direct indicator of the state of excitation of the weak transition³. Moreover, as the photon emission rate of the strong transition is very high, the photoelectron yield of a detector will, in first approximation, be equivalent to that generated by a steady beam of light with intensity I_0 ⁸. Similar couplings of quantum jumps to classical current pulses occur in SQUID analogue-to-digital converters⁹. The quantum jumps of the shelved electron may then be used to generate the telegraph signal shown in Fig. 2: the time intervals during which the signal is turned off (t_1, t_2 , etc.) indicate when the electron occupies state W ; the 'on' periods (T_1, T_2 , etc.) correspond to the rapid transitions $O \rightleftharpoons S$ that occur between the weak excitations of the electron from O to W .

In general, the time intervals for which the signal is off are distributed randomly with an exponential weight e^{-t/t_w} , where t_w is the decay time of the weak transition. If, as usual, A_w and B_w denote the coefficients for spontaneous and induced emission for the transition between W and O , and $U(\omega_{\text{weak}})$ is the spectral energy density of the incident ω_{weak} light, then this decay time is given by³: $t_w = [A_w + B_w U(\omega_{\text{weak}})]^{-1}$. Similarly, the time intervals for which the signal is on are distributed exponentially with weight e^{-T/T_w} , where $T_w = 2[B_w U(\omega_{\text{weak}})]^{-1}$. In principle, both of these stochastic sequences can be used to generate random numbers. For example, if the time intervals are rescaled in terms of the decay time, $\tau_i \equiv t_i/t_w$, the numerical sequence $\{e^{-\tau_i}\}$ is random and uniformly distributed in the interval $(0, 1)$. A measure of the fluctuations of the signal durations is given by the average magnitude of the difference between two arbitrarily chosen intervals, that is,

$$\langle |\tau_i - \tau_j| \rangle_{i,j} = \int_0^\infty \int_0^\infty d\tau_i d\tau_j |\tau_i - \tau_j| e^{-(\tau_i + \tau_j)} = 1 \quad (1)$$

We will shortly see that these and other statistical characteris-

Fig. 2 Fluorescence telegraph signal. The time intervals t_1, t_2, \dots, t_i during which the signal is 'off' correspond to the 'shelving' of an electron in state W; the signal is pulsed 'on' in the intervals T_1, T_2, \dots, T_i due to the strong fluorescence transitions between S and O.

tics of random exponential sequences can be simulated by deterministic algorithms. Furthermore, previous experience with analogue and hybrid devices in random-number generation has shown that these sources have correlational defects⁴. Therefore, before any serious attempts can be made to adapt the fluorescence telegraphs for the generation of random signals, it will be necessary to check to what extent the experimentally observed time sequences $\{t_i\}$ exhibit patterns of order. A crucial advantage of using single trapped objects with simple level structures as light sources is that various types of photon correlations, such as the Brown-Twiss effect^{10,11}, Fresnel biases in superfluorescent fluctuations¹² and cascade effects¹³, are suppressed. In addition, if the fluorescence is sufficiently intense, the photoelectron fluctuations in the detectors can be treated classically; in these circumstances the instrumental jitter in the length of the telegraph pulses $\{t_i\}$ should be negligible⁸. However, random drifts in the detector gains, reference voltages and laser intensities, and interactions between the stored objects and the trapping and cooling fields, are unavoidable. Experiments are needed to determine whether the net effect of these interactions is to introduce additional elements of order or disorder.

In either case the search for correlations can be facilitated by starting with situations in which the fluorescence telegraph signals contain well-defined messages. An experimental precedent is the modulation of radioactive decay by pressure variations. One instance is the decay of the isomer ^{99m}Tc : this transition is inhibited by large changes of angular momentum and an energy release of only 2 keV. Accordingly, the decay proceeds mainly by internal conversion and the rate is very sensitive to the overlap of the initial and final electronic wave functions. This overlap can be altered by pressure variations, so that, for example, the $\sim 2.16 \times 10^4$ s half-life of ^{99m}Tc can be shortened by ~ 4 s if the ambient pressure is increased to ~ 0.1 Mbar¹⁴. Clearly, if the pressure were regularly cycled on a timescale shorter than 6 h, the existence of such periodic variations could be inferred from a stochastic analysis of the decay sequences. Similarly, the fluorescence signals from stored ions can be modulated by varying the intensities of the double-resonance lasers or by cyclically altering the trapping fields. As experiments based on the shelved electron scheme have already been carried out with 1–3 trapped $^{24}\text{Mg}^+$ ions stored within optical coherence lengths, additional information on correlations and field gradients could be extracted from the telegraph signals^{1,11,15}.

At the core of all these technical variations there remains the basic quantum-mechanical prediction that the decay time of the W-state is a random variable with an exponential distribution; this can be demonstrated rigorously using only the very weak assumptions¹⁶. In the specific case of the fluorescence telegraph this exponential behaviour is not affected by quantum measurement problems such as the 'watched-pot' or Turing paradox and observational asymmetries between prediction and retrodiction^{17,18}. The only possible source of intrinsic correlations in double-resonance measurements is a long-term quasi-periodicity that might affect the population of the S-state: however, independent experimental evidence on this point is still lacking¹⁹.

The fact that single atoms with minimal interactions with the environment can, in principle, generate arbitrarily long strings of random numbers is another remarkable aspect of quantum

mechanics. According to algorithmic complexity theory it is precisely the generation of random numbers that requires the maximum amount of complexity. In particular, n bits of information are required to specify the construction of n random binary numbers^{5,20}. The inherent indeterminacy of quantum jumps therefore not only constrains the ultimate precision of measurements but also implies that even the simplest physical systems are equivalent to arbitrarily large reservoirs of information.

The search for order in the fluorescence telegraph signals also has a bearing on the role of random variables in quantum mechanics. In the standard axiomatic formulation of probability theory, a random variable is defined as a measurable function on a probability space—where the probability space is essentially a set endowed with a normalized measure. The axiomatic development is deliberately silent concerning any requirements that the measurable functions be non-determinate or that the elements of the probability space correspond to inherently unpredictable or erratic events. Indeed, the axiomatic structure has "... applications in fields of science that have no relation to the concepts of random event and of probability in the precise meaning of these words"²¹. This basic lack of distinction between random and pseudo-random processes has several practical consequences for the cryptanalysis of the telegraph signals: (1) Inherently random events can sometimes emulate ordered patterns: for example, there is a small but positive probability that any correlation or apparent 'message' in the telegraph signals may actually be an artefact of chance events; this is the essence of the 'monkeys typing Hamlet' situation²². (2) A more serious concern is that deterministic processes can mimic random events. There is an extensive hierarchy of deterministic functions—including mixing transformations and K-systems—that can simulate the stochastic behaviour of random processes²³. These functions have recently come to popular notice in connection with studies of 'chaos'. Furthermore, the probability distributions implied by the Schrödinger wave functions of many systems are the same as the distributions which are associated with certain mixing transformations²⁴.

The nominally random decay sequences $\{e^{-\tau}\}$ of the fluorescence telegraph can also be simulated by the iteration of mixing transformations. For example, the functions

$$f(\tau) = -\ln(|2e^{-\tau} - 1|) \quad (2a)$$

$$g(\tau) = -\ln(|3e^{-\tau} - 1| - 1) \quad (2b)$$

where $\tau > 0$, are the beginning of a countably infinite sequence of mixing transformations, each of which simulates an exponentially distributed random variable. This means that if we begin with any arbitrarily chosen value of τ , say $\tau = 3.15$, and compute the successive iterates, that is, $f(3.15) \approx 0.0896$, $f[f(3.15)] = f^2(3.15) \approx 0.1880$ and so on, then term-by-term the sequence $\{f^i(3.15)\}$ appears to vary erratically, but a histogram would show that the values are in fact distributed with exponential weight $e^{-\tau}$. This behaviour is illustrated in Table 1. The fluctuations of the deterministic sequences $\{f^i(\tau)\}$ and $\{g^i(\tau)\}$ also satisfy the statistical criterion given by equation (1):

$$\langle |f^i(\tau) - f^j(\tau)|_{i,j} \rangle = 1 \approx \langle |g^i(\tau) - g^j(\tau)|_{i,j} \rangle \quad (3)$$

A random sequence would still pass this test even if only successive values were chosen

$$\langle |\tau_{i+1} - \tau_i|_i \rangle = 1 \quad (4a)$$

but the deterministic sequences have correlations that yield slightly different averages ($0 \leq i \leq 10^5$):

$$\langle |f^{i+1}(3.15) - f^i(3.15)|_i \rangle \approx 1.09; \langle |g^{i+1}(3.15) - g^i(3.15)|_i \rangle \approx 0.92 \quad (4b)$$

Needless to say, more complicated simulations require more powerful cryptanalytical attacks to detect the underlying patterns of order.

Finally we consider the highly speculative question of whether there might be a physical basis for interpreting the randomness of quantum-mechanical variables in terms of the mixing gener-

Table 1 Simulation of exponential decay by a mixing transformation [equation (2b)]

τ	$g(\tau)$	$g^2(\tau)$	$g^3(\tau)$	$g^4(\tau)$	$g^5(\tau)$...

* Histogram derived from 10^5 iterations; bin size $\Delta\tau = 0.1$; $0 \leq i \leq 10^5$.

ated by the deterministic iteration of appropriate functions. In the specific case of the fluorescence telegraph, there are two suggestive possibilities: (1) Suppose first we assume that the trapped ions that generate these signals have access to only a finite number of physical states. In particular, if we identify these states with cells in phase space—each of size \hbar^3 —it is possible to estimate their number N . For example, if a trapped ion is localized in a sphere of radius 2,000 Å, and the electron transitions involve momenta bounded by 0.5 MeV c^{-1} , it is easy to check that the maximum number of accessible phase-space cells is $N \sim 10^{17}$. (2) Suppose further that the stored ion is sufficiently isolated from its environment so that it has access to only a finite amount of information²⁵. Physically this means that the net effect of the ion's interaction with the trapping fields, laser illumination and detectors is to induce a pseudo-random walk among the 10^{17} available phase-space cells. Under these conditions the telegraph sequences $\{e^{-\tau_i}\}$ will be deterministic simulations of a discrete random variable uniformly distributed in the interval (0, 1). It can then be shown that after roughly $i \sim \sqrt{\frac{1}{2}\pi N} \sim 4 \times 10^8$ electron shelvings—or cycles of decay and re-set—each of the sequences $\{e^{-\tau_i}\}$ will merge into a terminal loop with about $\sqrt{\frac{1}{2}\pi N}$ elements. Moreover, no matter which of the 10^{17} possible states happens to initiate a telegraph signal, there is an $80 \pm 1\%$ probability that the corresponding pseudo-random sequences $\{e^{-\tau_i}\}$ will merge into the same terminal loop⁶. The practical implication of these results is that if sufficiently long strings of signals are analysed, the existence of 'messages' or terminal loops will eventually be detected. Such messages are not contained in the usual formulation of quantum theory. Since the basic cryptanalytical signature of this type of deterministic behaviour is the repetition of patterns, the relative precision of the individual observations—such as the duration of the telegraph pulses t_i and T_i —does not of course have to be comparable to one part in 10^{17} or 10^8 !

We thank P. Hammerling for helpful discussions and G. Hockney for undertaking the computer simulations.

Note added in proof: A double resonance experiment with stored $^{198}\text{Hg}^+$ ions is currently being assembled at National Bureau of Standards (Boulder, Colorado). Its characteristics are: (1) lifetime of strong transition $\sim 10^{-9}$ s; (2) Rabi flopping frequency $\geq 10^7$ Hz; (3) photon collection efficiency $\sim 10^{-3}$; (4) number of photons detected per telegraph pulse $\sim 10^3$. Since this experiment is intended for precise frequency measurement the lifetime of the weak transition is ~ 0.1 s! A faster weak transition would facilitate the search for patterns (D. Wineland, private communication).

Dual emission-line regions in the Seyfert galaxy NGC 5929

William C. Keel

Kitt Peak National Observatory, National Optical Astronomy Observatories, PO Box 26732, Tucson, Arizona 85726-6732, USA

Several theoretical and empirical studies suggest that multiple distinct emission regions exist in the nuclei of some active galaxies. Detailed study^{1,2} of nearby objects such as M51 shows that the most important radiation of nonstellar origin can originate hundreds of parsecs from the nucleus (as defined by the stellar potential well), while binary compact objects are expected in some cluster-collapse schemes³ or in interaction-fuelled models for active nuclei^{4,5}. Here I show that the type 2 Seyfert nucleus of NGC 5929 contains two emission regions situated symmetrically about the centre of the galaxy. Slit spectroscopy shows them to be spatially as well as kinematically distinct, each with a linewidth of $\sim 200 \text{ km s}^{-1}$ and ionization levels normally associated with Seyfert nuclei. Their location in the galaxy's rotation curve suggests that they move with the galaxy's disk gas; and they probably result from energy transport from a central object of low photon luminosity but high energy output. This system furnishes a very clear example of the presence of phenomena related to the presence of a central engine, but located at a significant distance from the ultimate source of energy. The existence of such objects suggests that the usual radiatively powered, nearly symmetric models for active nuclei may be misleading in many objects.

Previous data on the Sab galaxy NGC 5929 indicated that two nuclei, or discrete emission regions, might be present. It was first identified as a type 2 Seyfert by the CfA group⁶. Intermediate-resolution aperture spectra (ref. 7 and J. Stauffer, personal communication) showed the emission-line profiles to be double-peaked. A Very Large Array (VLA) map at 6 cm by Ulvestad and Wilson⁸ showed emission dominated by two unresolved sources 1.3 arc s apart in position angle 60° , and some evidence for a weak source between them.

To confirm an association between the spatially distinct radio sources and kinematically distinct emission-line regions, a high-resolution spectrum has been obtained along the line defined by the radio sources. A Texas Instruments 800 × 800 charge-coupled device (CCD) was used with the Ritchey-Chrétien spectrograph on the 4-m Mayall telescope, covering the wavelength range 6,300–6,750 Å at a resolution (FWHM) of 2.0 Å , set by the slit width of 1.0 arc s . A 1-h exposure was obtained, resulting in peak levels of 700 counts (3,000 detected photons) per pixel (0.64 Å by 0.31 arc s) in the emission lines. The spectrum clearly shows two emission regions near the nucleus, kinematically and spatially separate (Fig. 1). The [O I] $\lambda 6,300$, 6,363 lines appear in both; this fact, the similar velocity widths ($\sim 200 \text{ km s}^{-1}$ FWHM), and high [O III]/H β in both components as found from previous data⁷, indicate that each of these regions has properties normally associated with active nuclei. The ionization levels are clearly most like type 2 Seyferts or narrow-line radio galaxies, despite the rather small linewidths. In this case, straightforward classification as a type 2 Seyfert may have obscured recognition of the unusual character of the

Fig. 1 The spectrum of NGC5929 in the region of $H\alpha$ and $[N II]$ $\lambda\lambda 6,548, 6,583$. The two emission regions are separated by 291 km s^{-1} and 1.3 arc s ; most of the spread along the slit is internal to the spectrograph camera. Additional weak emission between the two main peaks may be seen at $H\alpha$.

object, but the integrated line ratios and linewidths are certainly those associated with Seyfert nuclei.

Quantitative measures of the individual spectra have been performed by multiple-component gaussian fits to blended lines in each row of the spectrum, accounting for contamination of each spectrum by the other. The line ratios, relative strengths in $H\alpha$, and linewidths corrected for the instrumental profile are given in Table 1. Subtraction of the modelled components from the data provides some evidence of a weak, broad $H\alpha$ line at the centre of the galaxy; part of this emission may be seen between the $H\alpha$ peaks in Fig. 1. A comparison of the spectra of the two regions, obtained by taking the rows of the spectrum at the outer edges of each emission-line system to minimize scattered light from the other, is shown in Fig. 2.

Additional imaging data were obtained (in collaboration with R. Kennicutt) using the same CCD at the KPNO 2.1-m telescope. Exposures through filters with $75\text{-}\text{\AA}$ passbands centred on and off $H\alpha$ were obtained. Figure 3 shows the galaxy's morphology, its interacting companion NGC5930, and an enlarged portion of the $H\alpha + [N II]$ difference image. The emission-line structure is consistent with two unresolved centres of emission blended by seeing effects, with a separation close to that of the radio sources but a significantly different position angle ($\sim 85^\circ$). The structure is not consistent with a ring of emission, which might give similar spectroscopic results but a quite different physical picture.

From these data, several characteristics of the system are clearly established. Two dominant emission-line regions exist, each with a luminosity⁷ and ionization level sufficient for classification as a Seyfert 2 nucleus. They are separated by 1.3 arc s (projecting to 190 pc at an assumed distance of 34 Mpc derived by assuming $H_0 = 80 \text{ km s}^{-1} \text{ Mpc}^{-1}$), and have a radial-velocity difference of $291 \pm 11 \text{ km s}^{-1}$. The optical emission is nearly coincident with the pointlike radio sources. Finally, neither emission region coincides with the galaxy's dynamical centre; they fall instead along the rotation curve defined by disk $H II$ regions (easily traced in these data but not well seen in the low-contrast representation of Fig. 1), on either side of the nuclear velocity.

At least two plausible pictures are available to account for this configuration. Actual double nuclei, powered by separate compact objects, are occasionally expected when activity has been induced by a merger or cascading collapse of a stellar core to form compact objects. Gaskell⁹ has presented evidence for offset broad-line profiles in quasars, interpreted as evidence for merger-triggered activity, with the broad-line regions representing the cores of one of the original galaxies. In such a scheme,

Fig. 2 Cuts through the data of Fig. 1 at the top and bottom of the emission regions, showing the spectral properties of each free from contamination by scattered light from the other. The signal-to-noise ratio is consequently lower than that obtained at the peaks, where the images of the two regions overlap along the slit due to atmospheric and instrumental spread. The wavelength scale is in the frame of the dynamical centre of NGC5929, which has an observed radial velocity of $2,516 \text{ km s}^{-1}$.

one compact object would be expected at or very close to the centre of the dominant galaxy. In most cases, a large mass ratio for the compact objects would be expected, and probably reflected in the luminosities, simply because mergers of two galaxies with nearly equal masses of the central objects are unlikely, given the large range in level of nuclear activity seen at a given galaxy luminosity.

The picture is not likely to apply to NGC5929 for several reasons. The equal spacing of the emission regions about the dynamical centre of the galaxy implies that neither represents a central object which has long existed in this galaxy. The separation of the two emission regions is too large for a binary formed by core collapse, and probably too large to represent remnant cores in a merger which has had time to produce a normal disk. The presence of a central source of radio (and perhaps broad $H\alpha$) emission would not be naturally explained. Additional circumstantial evidence against a recent merger is the fact that NGC5929 is now seen interacting with NGC5930, so that a recent merger would require that the system now be seen at a very special time.

An alternative explanation is suggested by objects showing evidence for substantial unseen energy transport between the central engine and emission regions at distances from hundreds of parsecs (as in M51^{1,2}) to kiloparsecs (radio galaxies¹⁰). The detected emission regions in these cases seem to be powered by the nucleus, but through a beamed (or 'fanned') mechanism analogous (and perhaps identical) to jets¹¹. NGC5929 may be considered within this framework as an unusually clear example of traditional active regions powered by the nucleus while lying at some distance from it. The weak central source seen at 6 cm and suspected at $H\alpha$ would then be radiation from the immediate vicinity of the central engine, while the total output of the nuclear region is dominated by twin emission regions which convert nuclear (radiation or particle) beams into line radiation (with some continuum seen at least in the radio).

The offset between radio and emission-line peaks, in this

Table 1 Emission-line systems in the nucleus of NGC5929

Line ratio	NE	SW
$[N II] \lambda 6,583/H\alpha$	0.51	0.67
$[S II] \lambda\lambda 6,717, 6,731/H\alpha$	0.59	0.81
$[O I] \lambda 6,300/H\alpha$	0.18	0.31
$[S II] \lambda 6,717/\lambda 6,731$	1.14	1.11
Relative $H\alpha$ flux	0.48	0.52
FWHM (km s^{-1})	174	192

Fig. 3 NGC 5,929/5,930 as observed in a 75-Å passband including H α . The orientation and width of the spectrograph slit used to obtain the data of Figs 1 and 2 are shown by the black lines. Inset, an enlargement of the nucleus of NGC 5929 after subtraction of a continuum image, yielding a pure emission-line image. The bright portion of this image is consistent with two sources unresolved at the 1 arc s level, separated by ~ 1.2 arc s.

picture, presumably indicates that the radio peaks mark the sites of most intense ionization by the nuclear jets (or other, still collimated, forms of energy transport). The extent of optical emission is governed as much by the availability of gas as by the amount of energy available to power the emission. As there is no clear mechanism by which the directions of energy output from the nucleus should be coupled to the disk rotation 100 pc away, a 'tail' of excited material can develop as new matter is brought into the beams. The emitting clouds will become misaligned by a measurable amount with their starting points in $\sim 10^5$ yr; if the gas at $n_0 \approx 10^3 \text{ cm}^{-3}$ survives longer than this after first being ionized by the nucleus, a characteristic S-shaped configuration (like that frequently attributed to precessing jets) will be seen in the emission lines; when not resolved, this would lead to an observed centroid position offset from the points of current energy input.

If the nucleus supplies energy to the emitting region primarily in particles, they may have a role in producing the observed densities of gas through compression of the existing interstellar medium, and may also contribute to the internal velocity dispersion of the clouds. If the particle beams take the form of discrete plasmons, which would be seen directly as the 6-cm sources, the model elaborated by Pedlar *et al.*¹² to account for the densities and velocity widths in Seyfert 2 nuclei as a class might apply. In this model, the expanding plasma clouds compress the surrounding interstellar medium during thermal expansion; the medium cools after the expansion slows below $\sim 400 \text{ km s}^{-1}$ to produce the emission-line region. Some analogous process, whether discrete or continuous ejection takes place, is quite likely to be active in NGC 5929.

The properties of this nucleus suggest interesting implications for other active nuclei. Most narrow-line regions remain spatially unresolved, especially in distant, high-luminosity objects. If excitation by beams, in addition to direct photoionization from the nuclei, is important, elongated or double emission regions may be quite common, and are to be expected in some abundance with the resolution attainable with the Space Telescope. Also, note that the genuine compact object in NGC 5929, identified as the 6-cm central component and perhaps a broad H α source, is very inconspicuous, and would be difficult to detect in the absence of a surrounding gaseous disk to produce the prominent narrow-line regions. Linking statistics of active nuclei with those of central compact objects will clearly require detailed knowledge of the gaseous environments of the nuclei involved.

These data indicate that nuclear activity in galaxies can take forms significantly different from the picture developed for most

Seyfert galaxies, in which a central source of ionizing photons powers a more or less spherical ensemble of surrounding gas clouds, which then produce the emission-line spectrum. In at least some cases, the emission-line regions can be far from the energy source and dynamical centre of the galaxy, and a large part of the energy supply for these regions is asymmetrically generated by the central object. Note that if only one of the emission regions were present in NGC 5929, its peculiarity would not have been detected without considerably more detailed investigation. In at least one other galaxy, NGC 2110, the emission-line intensity and width peak at a projected distance of 220 pc from the kinematic centre¹³. In view of the results for NGC 5929, it may be argued that such objects as NGC 2110 contain 'one-sided' counterparts of the double emission-line region, and that more active nuclei may exhibit such properties when observed at high spatial resolution.

I thank Nigel Sharp, Jay Gallagher and Jean Goad for discussions, and G. Will and V. Junkkarinen for assistance at the telescope. The imaging data were obtained as part of a collaborative program with R. C. Kennicutt Jr. The National Optical Astronomy Observatories are operated by the Association of Universities for Research in Astronomy, Inc., under contract with the NSF.

An early-medieval account on the red colour of Sirius and its astrophysical implications

Wolfhard Schlosser* & Werner Bergmann†

Department of * Physics and Astronomy and † History, Ruhr-University Bochum, Postfach 10 21 48, D-4630 Bochum 1, FRG

An unresolved problem regarding ancient astronomical records is that of the star 'Red Sirius'. While Sirius today shines white with a blueish hue quite in agreement with its spectral type A1V, many Greek/Roman and Babylonian sources (although still disputed) definitely assign a red colour to this star. We now present new and apparently independent information about Red Sirius from an early-medieval manuscript. This manuscript is of Lombardic origin (8th century) and contains the otherwise lost 'De cursu stellarum ratio' by Gregory of Tours (about AD 538-593). It is preserved in the library of Bamberg¹. Red stars in ancient records are those with colour index $B - V = 1.0$ or greater. Assuming an unchanged Sirius A, this lower limit for the combined colour of Sirius A and B allows the computation of the region of pre-white dwarf Sirius B in the Hertzsprung-Russell diagram or colour-magnitude diagram (Figs 1, 2). Sirius B lies on the giant branch, which fits well with our observational and theoretical framework of stellar evolution. However, the timescale of transformation of a red giant to a white dwarf is surprisingly short.

In antiquity, Sirius was considered generally as a red star. A well-known case is Ptolemy's reference to Sirius as 'reddish' in his *Almagest*. Other classical authors, including Cicero, Horace and Seneca, concur with this opinion. Less well known is the

Fig. 1 Observed Hertzsprung-Russell diagram for luminosity classes III and V (after ref. 7). The variable width of each sequence indicates its varying population. The giant branch (III) runs into the region of the hypothetical red companion of Sirius A. Conversion of colour into spectral class is after ref. 9.

fact that the Romans sacrificed red-coated dogs to Sirius at the time of its heliacal rise².

The red colour of Sirius in antiquity is further substantiated by many Babylonian cuneiform texts. In his *Planetarium Babylonicum*, Gössmann³ quotes many astronomical and astrological qualities attributed to Sirius. (We follow Gössmann's translation, although not all scholars agree on the assignment of Babylonian terminology to its modern equivalent (see, for example, ref. 4).) If a colour is given, it is always red. Far-Eastern texts do not give any hint of a colour change for Sirius.

Since such a marked change of colour within historical times seems hard to accept, two alternative explanations were considered. The first one attributes the colour change to atmospheric reddening. Within 3° of elevation above horizon, Sirius indeed assumes or even exceeds the red colour of Betelgeuze. This, however, is restricted to 15 min after rising or before setting and is by no means representative of the 11-h diurnal arc of Sirius. The second argument is based on colour scintillation, which randomly changes the colour of bright stars close to the horizon. Here, simple observations of this phenomenon confirm intuitive physical insight: a white star produces as many red flashes as green or blue ones.

One should also remember that Sirius is not the brightest body in the sky. Leaving out the Sun and Moon, Sirius ranks fourth after Venus, Jupiter and Mercury, where no such controversy exists.

We have now found new information about the Red Sirius while analysing Gregory of Tours' *'De cursu stellarum ratio'*. The purpose of this work was to furnish monasteries with clear instructions on when to conduct nocturnal divine services, and for this, the rise-times of certain constellations for different months are listed. Since Gregory of Tours lived about one century before the rise of Islam, no Arabic star names appear in the manuscript, but none of the well-known classical names still in use today is used either, so this source reflects an astronomical tradition independent of classical or Babylonian skylore.

In this merovingian text, Sirius is easily identified by its rise-times and times of visibility. It is called 'stella splendida', the only case in the manuscript where this attribute of highest luminosity is given. Its proper name is 'Rubeola' or 'Robeola', meaning 'red' or 'rusty'.

This new and seemingly independent evidence for the red colour of Sirius in the past suggests that there might indeed have been an astrophysical transformation of the Sirius A/B system during the past two millennia. From an astrophysical viewpoint, the white dwarf Sirius B is the better candidate for such a change, since white dwarfs are thought to be the result of a collapsed red giant.

The total brightness of an unresolved binary system is obtained simply by adding up the intensities of each component.

Fig. 2 Computed evolution of stars of the same age but different masses ($0.6-3 M_{\odot}$) from main sequence to the region of red giants (arrows). The direction of evolutionary tracks coincides well with predicted pre-white dwarf Sirius B colours and magnitudes. (Simplified after ref. 8 for 30% helium content and 1% heavier elements.) The numbers refer to ages in $\text{yr} \times 10^8$. Present-day Sirius A lies well on the main sequence, a further hint of its stability during the past two millennia.

Basically, the same is true for the colours. Thus, a colour-magnitude relation for Sirius B in the past may be computed by assuming an unchanged Sirius A and guessing the colour of the combined light. In antiquity, the following stars were considered to be red (Sirius excluded); Betelgeuze ($B-V=1.9$), Antares ($B-V=1.8$), Aldebaran ($B-V=1.5$), Mars ($B-V=1.4$), Arcturus ($B-V=1.2$) and Pollux ($B-V=1.0$). (All colours $B-V$ are from refs 5, 6.) Since Ptolemy's Almagest assigns no specific colour to α Centauri ($B-V=0.7$), a lower limit of $B-V=1.0$ is probably a good approximation for stars called 'red' in antiquity. Using this lower limit, a straightforward computation confines Sirius B to the region specified in Figs 1 and 2. It agrees well with the giant branch in the observed Hertzsprung-Russell diagram⁷ and the evolutionary tracks of a broad variety of stellar masses according to theoretical astrophysics⁸.

If Sirius was redder in antiquity, it must also have been brighter. Taking absolute visual magnitude, $M_V = +1.43$ for Sirius A and assuming $M_V = -1.0$ for Sirius B before change (Figs 1, 2), one obtains $M_V = -1.11$ for the combined light. With a distance modulus $m-M = -2.89$ this gives a total magnitude of -4.0 , which is about that of Venus. Like Venus, Sirius should have been visible in daylight under favourable conditions. Indeed, several Babylonian sources mention the daytime visibility of Sirius³.

Thus, Sirius B might well have changed from a red giant to the white dwarf as it appears today. However, the rapidity and smoothness of this transformation are quite unexpected, and its timescale is surprisingly short. Furthermore, no traces of catastrophic effects connected with such an event have been found. The only indication that something has happened is the somewhat higher metallicity of Sirius A, believed to have resulted from contamination by the giant's blown-off shell.

Possible nightside source dominance in nonthermal radio emissions from Uranus

S. A. Curtis

Planetary Magnetospheres Branch, NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

Desch and Kaiser¹ have formulated a radiometric Bode's law from which they have attempted to estimate the low frequency, non-thermal radio power of Uranus' magnetosphere likely to be measured by the Voyager 2 spacecraft as a function of the planet's magnetic moment and the solar wind power input. They have in essence calculated what are possible necessary conditions for the generation of radio emission from Uranus. A potential problem arising from this calculation is that although their model for uranian radio emission may represent necessary conditions, they are not sufficient. I show here that, if Uranus possesses a magnetosphere, it is more likely that the radio emission is from the nightside as opposed to the dayside as assumed by Desch and Kaiser. A nightside source for the radio emissions would radically alter the predicted time for first observations of the emissions.

If a spacecraft were to approach the Earth, whose emission source is on the near-midnight high latitude nightside, from the inside its orbit, or if it were to approach Saturn, whose emission source is on the near-noon, high latitude dayside from outside its orbit, in both cases emissions would not be detected until very near encounter. Thus, although the power levels at both planets exhibit a degree of scalability, they have very different emission regions and directions that would affect any attempted predictions based on power levels alone. Earlier related work by Hill and Dessler² whose main point was to explain the ultraviolet auroral emissions using a somewhat different magnetospheric structure, qualified their predictions concerning radio emissions. In particular, they noted the uncertainty in the interpretation of the radio emissions owing to differences in beaming geometries between the planets.

One does indeed require an overall power input to a planetary magnetosphere to provide the free energy to drive planetary radio emissions. However, this energy still needs to be put in a usable form, generally field-aligned fluxes of weakly relativistic keV electrons in a region where the electron plasma frequency to electron gyrofrequency ratio, $\omega_{pe}/\omega_{ce} < 1$ (refs 3–5). More specifically, Benson⁶, using ISIS-1 satellite observations of the Earth's auroral kilometric radiation (AKR) has shown that $\omega_{pe}/\omega_{ce} < 0.2$ for the generation of extraordinary (X) mode radiation. Benson also deduced generation of weaker ordinary (O) mode radiation is allowed for $\omega_{pe}/\omega_{ce} \leq 0.9$. Since $\omega_{pe}/\omega_{ce} = 3.21 \times 10^{-3} n_E^{1/2} B^{-1}$, where n_E is the electron density in cm^{-3} and B is the magnetic field in gauss, the ω_{pe}/ω_{ce} limits of Benson yield constraints on the generation of low frequency radio emission on Uranus.

A unique aspect of Uranus is compared to Earth, Jupiter and Saturn is its near pole-on orientation towards the Sun and possible magnetic pole orientation in nearly the same direction. The possible existence of an intrinsic magnetic field has been revealed by the International Ultraviolet Explorer (IUE) spacecraft's⁷ apparent detection of uranian auroral emission that are consistent with a magnetosphere. The region of open field lines called the cusp that allows access to the ionosphere of Uranus by the shocked solar wind is thus located near the subsolar point of the planet as opposed to higher latitudes at Earth, Jupiter and Saturn. Magnetosheath plasma may thus have more direct access to the ionosphere via the cusp throat than at Earth. Given the collisional ionosphere at the base of the cusp and the cross-magnetic field transport required to move plasma outward through the cusp walls, we see that, unless a strong convective electric field is set up by solar wind/magnetosphere interaction, the cusp plasma will act as a local plasma source for the ionosphere at its base. We note that the magnitude of the cusp plasma source may be highly variable owing to solar wind dynamical evolution by entrainment and pressure waves as

discussed by Burlaga *et al.*⁸. Additionally, if these density variations are sufficiently great, the situation may become similar to the immersion of Saturn in the jovian tail⁹ and no substantial emission would be expected from Uranus in the low density solar wind troughs.

For X-mode generation we have the constraint $n_E < 3.9 \times 10^3 B^2$, and similarly for O-mode, $n_E < 7.9 \times 10^4 B^2$. Hence for $B = 0.1$ gauss (Earth-like), $n_E \geq 39 \text{ cm}^{-3}$ will suppress X-mode and $n_E \geq 790 \text{ cm}^{-3}$ will suppress O-mode also. These are very low densities for a dayside topside ionosphere with the additional cusp plasma source and unless the magnetic field is strong (≥ 1 gauss), it appears that both emission modes will be suppressed.

An additional limitation posed by high cusp electron densities is the difficulty in maintaining field-aligned electric fields needed to produce the energetic keV electron fluxes. The high densities will tend to short them out and preclude wave trapping acceleration mechanisms as have been proposed for producing field-aligned keV electron fluxes by Hasegawa¹⁰ which are needed for the Earth's AKR.

Having shown that it is plausible that a dayside source of uranian radio emission does not exist, I next consider possible nightside generation. In this case the cusp densities should be much reduced owing both to the lack of photoionization as well as the inhibition of transportation of dayside ionospheric plasma to the nightside across magnetic field lines. Thus if $B \sim 0.1$ gauss Earth-like auroral zone type densities should be possible with $\omega_{pe}/\omega_{ce} < 1$ if $n_e < 10\text{--}100 \text{ cm}^{-3}$. Thus strong emission will occur provided the keV electron fluxes can be produced in sufficient quantity. To explore this, I examine two limiting cases of the uranian magnetosphere. These two cases represent (1) the limits of high mass loading due to pickup plasma by the magnetosphere from the planet's satellites resulting in a rotationally driven, convection-dominated magnetosphere¹¹ like Jupiter and Saturn or (2) at the opposite extreme, no mass-loading and a Faraday disk dynamo magnetosphere¹². In the first case the emissions may be expected to be dominated by plasmashet related MHD instability processes and electron acceleration by wave-trapping as they apparently are at Saturn¹³. In contrast, in the low mass-loading limit, one would expect the Kelvin-Helmholtz instability operating on the magnetopause boundary to generate field-aligned surface MHD waves. Through mode conversion¹⁰, these waves will trap and similarly accelerate magnetosheath electrons into the nightside cusp/magnetosphere boundary region. Since the waves will only be driven nightward, the electrons will be accelerated only in the direction of the nightside pole. This limiting case presents some difficulties if the IUE observations are correct, since only a nightside auroral and radio emission would be expected. In contrast, in the high mass-loading limit, the centrifugally driven plasmashet interchange instabilities can drive surface waves that can accelerate electrons into both dayside and nightside cusp regions. In this case, since $\omega_{pe}/\omega_{ce} > 1$ in the dayside cusp-magnetosphere boundary region, only aurora would be generated on the dayside. However, both aurora and radio emission can be generated on the nightside where $\omega_{pe}/\omega_{ce} < 1$ is likely. Hence, the dominant radio emission from Uranus is expected from the nightside cusp-magnetosphere boundary region, which should not be observed until uranian encounter. We also note that of the dayside aurora of Uranus are genuine, mass-loading of the magnetosphere by its satellites is probably an important process within the framework presented here. If, however, planetary rotation and magnetic merging combine to give a large enough helical twist to the tail field lines, the resulting Birkeland currents that flow into the dayside polar cap may give rise to a dayside polar aurora even in the low mass-loading limit¹².

In conclusion, it is not possible to exclude either the Desch and Kaiser, or the Hill and Dessler power scaling relations. Clearly, however, their predictive power is marginal in that all of these authors have assumed a dayside radio emission source on Uranus which may, according to the arguments presented here, be either very weak or non-existent.

Predicted chemistry of the deep atmosphere of Uranus before the Voyager 2 encounter

Bruce Fegley Jr & Ronald G. Prinn

Department of Earth, Atmospheric, and Planetary Sciences,
Massachusetts Institute of Technology, Cambridge,
Massachusetts 02139, USA

The Voyager 2 spacecraft will encounter Uranus in January 1986, and will provide the first spacecraft observations of that planet. It carries an infrared interferometer spectrometer (IRIS) which has already detected a variety of infrared active gases in the atmospheres of Jupiter, Saturn and Titan¹⁻⁴. Some of the detected gases are not in chemical equilibrium but have sources in the deep atmosphere. IRIS observations of these non-equilibrium gases, in particular PH₃ (mixing ratio $X_{\text{PH}_3} \approx 6 \times 10^{-7}$) and GeH₄ ($X_{\text{GeH}_4} \approx 7 \times 10^{-10}$) on Jupiter¹ and PH₃ ($X_{\text{PH}_3} \approx 1 \times 10^{-6}$) on Saturn³, can be used to deduce the strength of convective mixing in the deep atmospheres of Jupiter and Saturn^{5,6}. Similar deductions could be made about convective mixing rates in the deep atmosphere of Uranus if models of the equilibrium chemistry and thermochemical kinetics were available to help interpret IRIS observations of the visible Uranus atmosphere. We describe here the results of comprehensive thermochemical equilibrium and chemical kinetic calculations for Uranus. We predict that the most abundant non-equilibrium trace gas derived from the deep atmosphere of Uranus is N₂; other important non-equilibrium species include HCl, HF, GeH₄, C₂H₆, PH₃, H₂Se, CH₃SH, CO, CH₃NH₂, CH₃OH, and CO₂. Some of these species are detectable potentially by the Voyager instruments.

We assume that Uranus, like Jupiter and Saturn, has a deep convective atmosphere. Use of this assumption also leads to reasonable interior structure models⁷, but this is still uncertain because of the apparent lack of a large internal heat source on Uranus⁸. The present results refer to an arbitrary but plausible compositional model in which H₂ and the noble gases (He, Ne, Ar, Kr, Xe) are present in solar abundance⁹, H₂O, NH₃, H₂S and many 'heavy' elements (atomic number ≥ 3) are enriched 100 times relative to solar abundance, and CH₄ is enriched ≈ 10 times. This model, which is based on the low-temperature equilibrium condensation sequence outlined by Lewis¹⁰ and Prinn and Fegley¹¹, is one of several that we are investigating. It is consistent with deductions from visible¹² and infrared¹³ spectroscopy and interior structure models⁷ that Uranus is enriched in 'heavy' elements relative to solar abundances.

We constructed an adiabatic temperature-pressure profile for our model Uranus atmosphere taking temperature $T = 74$ K at pressure $P = 1$ bar (ref. 13). Thermochemical equilibrium calculations were done for several hundred compounds of the elements H, He, O, C, N, S, Fe, Mg, Si, Na, Cl, K, F, P, Ge, Se, Ne, Ar, Kr, Xe, Ca, Al and Ti. The thermochemical kinetics of the important destruction reactions for selected gases were also studied. Homogeneous gas phase and heterogeneous Fe-catalysed destruction reactions for N₂ and CO were included in our model. The specific techniques used to construct our model and the thermodynamic and chemical kinetic data sources are described in detail elsewhere^{5,6,11,14-18}.

The calculated equilibrium mixing ratios of important gases as functions of temperature and pressure are illustrated in Fig. 1. The abundances of two major gases H₂O and NH₃ are appreciably reduced by the formation of dilute NH₃-H₂O solution clouds at 595 K. By the 275 K level the NH₃ abundance is less than the H₂S abundance and it is quantitatively removed from the atmosphere by precipitation of NH₄HS(s) as first suggested by Prinn and Lewis¹⁹. X_{NH_3} varies from about 10^{-9} at 200 K to 10^{-14} at 160 K, compatible with the observations of Gulkis *et al.*²⁰ that NH₃ is depleted in this region of the Uranian atmosphere. Atreya and Romani²¹ and Stevenson²² also noted that formation of NH₃-H₂O solution clouds would consume large amounts of NH₃. The excess H₂S may condense slightly higher in the atmosphere at 166 K but is probably photolysed to S₈(s) on a short timescale, while CH₄(s) condenses at 77 K. The equilibrium abundances of other gases such as HCl, HF, H₂Se, GeH₄ and P₄O₆ are reduced significantly by precipitation reactions lower in the atmosphere (see Fig. 1).

Larger enhancements of H₂O will yield solution cloud condensation at higher temperatures (and deeper levels) of the

Fig. 1 Equilibrium abundances of important gases along the model adiabat in the atmosphere of Uranus. The horizontal scales indicate temperature, depth below the 300 K level and pressure along the adiabat. The constant abundances of the noble gases ($X_{\text{Ne}} = 1.5 \times 10^{-4}$, $X_{\text{Ar}} = 6.1 \times 10^{-6}$, $X_{\text{Kr}} = 2.4 \times 10^{-9}$ and $X_{\text{Xe}} = 3.4 \times 10^{-10}$) are not plotted. Precipitation of NH₄Cl(s), NH₄F(s), NH₄H₂PO₄(s), Ge(s) and GeSe(s) at 629 K, 430 K, 602 K, 868 K and 339 K, respectively, depletes HCl(g), HF(g), P₄O₆(g), Ge gases and Se gases. Solution of H₂S(g) and HF(g) in the ammonia-water clouds is a minor effect. All compounds of Fe, Mg, Si, Na, K, Ca, Al, Ti are condensed phases over the (P, T) range considered.

Fig. 2 *a*, Predicted N_2 and CO mixing ratios in the observable uranian atmosphere as a function of the vertical eddy diffusion coefficient K . Homogeneous gas-phase and heterogeneous iron-catalysed reactions are considered. Curves for catalysis on iron cloud particles with radii of $10\ \mu\text{m}$ (CO) and $1\ \mu\text{m}$ and $10\ \mu\text{m}$ (N_2) are shown. The dotted line on the CO heterogeneous curve indicates the predicted trend in the absence of homogeneous gas-phase reactions. Actual CO mixing ratios for $K < 5 \times 10^9\ \text{cm}^2\ \text{s}^{-1}$ will follow the homogeneous curve. *b*, As *a* but for PH_3 , GeH_4 , HCN and CO_2 . Homogeneous gas-phase reactions only are considered.

uranian atmosphere until the H_2O critical point of 647 K is reached. Because the initial clouds are very dilute NH_3 - H_2O solutions which have critical points slightly lower than that of pure water²³, the 647 K level is the upper temperature limit to a NH_3 - H_2O solution cloud base on Uranus. Latent heat effects due to solution condensation will also decrease as the cloud-base temperature approaches the critical point for the first formed (dilute NH_3 - H_2O) solution^{24,25}.

The observations of PH_3 and GeH_4 on Jupiter¹ and of PH_3 on Saturn³ at concentrations orders of magnitude greater than their equilibrium abundances in the cool visible regions of the jovian and saturnian atmospheres have been interpreted in terms of rapid convective mixing from the hot deep atmospheres where these species are more abundant^{5,6,14}. We have applied a similar model to Uranus to predict concentrations of non-equilibrium gases such as N_2 , GeH_4 , PH_3 , CO, CO_2 , and HCN in the uranian upper atmosphere as a function of the rates of the relevant homogeneous and heterogeneous destruction reactions and the (assumed) strength of convective mixing in the deep uranian atmosphere. Iron-catalysed heterogeneous $N_2(g)$ and $CO(g)$ destruction reactions were considered using the model of Prinn and Olaguer¹⁷. This treatment gives firm lower limits to the N_2 and CO mixing ratios, because Fe(liquid) condenses at 6,000 K (2.4×10^7 bar) so Fe particles in the 1,000–2,000 K region are unlikely. The results of these calculations are illustrated in Fig. 2 where the predicted mixing ratios are plotted as a function of the vertical eddy diffusion coefficient K .

No observational estimates are available for the vertical eddy diffusion coefficient K in the deep uranian atmosphere. However, various *a priori* estimates of K are possible. Assuming that free convection is a dominant mode for vertical heat transport in the deep uranian atmosphere, we can estimate K from the relationship, $K \approx H(\phi/\rho\gamma)^{1/3}$ where H is the pressure scale

Table 1 Predicted non-equilibrium trace gas abundance in the observable atmosphere of Uranus for 100 times enriched compositional model ($K = 10^7$ – $10^8\ \text{cm}^2\ \text{s}^{-1}$)

Gas	Quench temperature (K)	Predicted mixing ratio
N_2	1,205–1,390	$(5.0\text{--}6.3) \times 10^{-5}$
PH_3	1,058–1,102	$(1.0\text{--}2.3) \times 10^{-7}$
GeH_4	775–810	$(5.0\text{--}10) \times 10^{-8}$
CO	846–885	$(3.2\text{--}10) \times 10^{-11}$
HCN	1,299–1,357	$(1.6\text{--}3.5) \times 10^{-10}$
CO_2	787–832	$(3.2\text{--}10) \times 10^{-12}$

height, γ is the ratio of the heat capacity at constant pressure to the gas constant, ρ is the atmospheric density, and ϕ is the upward heat flux carried by free convection. Taking $\phi \approx 10$ – $100\ \text{erg cm}^{-2}\ \text{s}^{-1}$ from ref. 26 yields $K \approx (5\text{--}10) \times 10^7\ \text{cm}^2\ \text{s}^{-1}$ at the 1,000 K level in our atmospheric model. These values suggest more sluggish convective mixing on Uranus than on Jupiter or Saturn where $K \approx 10^8$ – $10^9\ \text{cm}^2\ \text{s}^{-1}$ in the deep atmosphere^{6,16,27–29}.

Table 1 shows the predicted abundances of N_2 , CO, PH_3 , GeH_4 , HCN and CO_2 in the observable Uranus atmosphere for $K \approx 10^7$ – $10^8\ \text{cm}^2\ \text{s}^{-1}$. Specific kinetic calculations were not done for other potential non-equilibrium gases such as C_2H_6 , CH_3SH , CH_3NH_2 and CH_3OH , but quench temperatures of $\approx 1,000$ K may not be unreasonable for these gases³⁰; the resulting abundances can then be estimated from Fig. 1. Since precipitation of $NH_4Cl(s)$ and $NH_4F(s)$ may be very difficult to quench, HCl and HF are likely to be in equilibrium; however, if the low NH_3 mixing ratios ($< 10^{-6}$) inferred by Gulkis *et al.*²⁰ hold throughout the uranian atmosphere there will not be enough NH_3 to react with the HCl and HF, so their equilibrium concentrations could be much higher than indicated in Fig. 1. Non-ideal gas behaviour may increase the pressure-dependent N_2 abundance; at our highest N_2 quench temperature (1,390 K), the pressure may be three times too high³¹ and thus the predicted N_2 abundance nine times too small, while at lower temperatures the required corrections becomes smaller.

Once the Voyager observations are in hand, the inverse process, namely deduction of K values from the observed abundances of PH_3 , GeH_4 and so on, will be possible using Fig. 2.

Steam rapidly reduces the swelling capacity of bentonite

Rex A. Couture

Chemical Technology Division, Argonne National Laboratory,
Argonne, Illinois 60439, USA

Sodic bentonite is widely used for industrial and scientific purposes, especially as a sealing agent¹, because of its great ability to swell in water^{2,3}. It has been proposed for use in high-level nuclear waste repositories as an impermeable barrier surrounding the waste package, or to fill tunnels, shafts and rooms. In some repositories, such as those planned in basalt, bentonite would be expected to be subjected to temperatures possibly up to 300 °C (refs 4, 5). As the waste would be approximately 600-900 m below the water table in fractured rock, the repository is expected to fill first with steam and then with liquid water^{4,6}. Reaction of bentonite with liquid water produces a minimal loss of swelling capacity, but I show here that reaction with water vapour at 150-250 °C results in rapid irreversible loss of most of the swelling capacity. This causes very large increases in permeability of sand-bentonite mixtures⁷, thereby reducing the ability of a bentonite barrier to retard the flow of groundwater in proposed high-level nuclear waste repositories.

The thermal and hydrothermal stability of bentonite has been repeatedly questioned^{6,8-10}, but transformations generally are expected to be slow enough and the duration of high temperatures brief enough that bentonite is not necessarily disqualified for use in a repository at high temperatures^{5,9,10}. Furthermore, in some environments, transformation may be limited by availability of potassium or other elements⁹⁻¹¹. In typical

hydrothermal experiments, montmorillonite was structurally unaltered, but underwent compositional changes after reaction with basaltic groundwater for 96 days at 360 °C, 30 MPa (ref. 10), and after reaction with basalt plus groundwater for 379 days at 300 °C, 30 MPa (ref. 5). Large reductions in the ion-exchange capacity¹² and small reductions in the swelling ability^{13,14} of bentonite were observed after heating to temperatures of 100-300 °C, but irreversible dehydration, which would imply a major mineralogical change, was not observed after heating for 340 days at 370 °C (ref. 5).

On the other hand, rapid and severe reduction in the swelling ability of bentonite because of exposure to steam has recently been observed⁷. In a series of experiments the permeability of sand-bentonite mixtures (25% bentonite, 75% basalt or quartz sand, with dry bulk densities of ~1.6 g cm⁻³), as measured by flow of liquid water, increased by up to 10⁵ as a result of prior exposure to water vapour at temperatures between 250 °C and 260 °C (ref. 7). The increase in permeability was due to a large, irreversible decrease in the swelling capacity of the bentonite. Here I present data on the effects of water vapour on bentonite at temperatures between 150 °C and 250 °C.

The methods and results are shown in Table 1. The untreated bentonites swell to very high specific volumes in water. For example, Envirogel expands to a specific volume of 37 ± 4 cm³ g⁻¹, and forms a thick gel at specific volumes of 30 cm³ g⁻¹ or less. The maximum specific volume in water is defined here as the swelling capacity.

Dry heating to 250 °C for 7 days with no added water seems to reduce the swelling capacity slightly (sample 5), as observed previously^{13,14}. This reduction may have resulted from reaction with water of hydration before the sample dried, as the following experiments suggest.

Heating the bentonite to 250 °C in a closed system, with a limited amount of water, caused a great change in wetting and swelling behaviour. The unreacted material forms a sticky, gummy paste when mixed with water, but the reacted material is not cohesive in water, and has greatly reduced swelling capacity (samples 6-11, 19-21). All four bentonites were affected similarly. Bentonite initially contains about 8% water of hydration; even this amount of water, if retained during heating, is enough to severely alter the swelling properties of the bentonite

Table 1 Effects of heat and water vapour on swelling capacity of bentonite

Sample no.	Bentonite	Mass of bentonite (g)	Water added (g)	Water composition	Temperature (°C)	Total water* bentonite	Swelling capacity (cm ³ g ⁻¹)

21	National Standard	4.84	0.34	dw	250	0.15	11

Samples of bentonite were reacted with deionized water (dw) or basaltic groundwater (gw) for 5-7 days (5 days for samples 5 and 11; 7 days for the others) in small stainless steel or Inconel autoclaves. The composition of the groundwater was 3.0 mM NaCl, 2.0 mM Na₂SiO₃, 2.0 mM NaF, 1.1 mM Na₂SO₄, 0.7 mM NaHCO₃, 0.6 mM Na₂CO₃, 0.03 mM CaSO₄, adjusted to pH 9.9 with HCl. The autoclave volumes were 7.6-7.9 cm³, except for sample 20 (5.4 cm³). After reaction, the swelling capacity of the clay was determined by dispersing 0.10-0.15 g (dry weight) of clay ultrasonically with 4 ml of water in graduated conical centrifuge tubes at ~22 °C, allowing the clay to settle and measuring the expanded volume. The expanded volumes did not change after several months of standing. The error in swelling capacity is ±10%. The temperature accuracy is ±5 °C. The bentonites were from the following sources: Envirogel, Wyo-Ben, Inc.; SWy-1, Clay Minerals Society; Montmorillonite 27, Ward's Natural Science Establishment, similar to American Petroleum Institute Montmorillonite 27; National Standard, Baroid Corporation. Except for samples 12 and 16, the only pretreatment of the bentonite consisted of drying, crushing and sieving by the suppliers. Except for quartz and plagioclase, the samples were nearly pure montmorillonite, with sodium as the predominant exchangeable cation. Smaller amounts of potassium feldspar (probably sanidine), illite or mica, calcite, gypsum and apatite were also present. Most of the experiments were done with Envirogel (Wyo-Ben, Inc.), which contains ~80% montmorillonite and is described elsewhere¹⁰. Purified Envirogel (sample 12) was prepared by sedimentation in water to remove about 20% sand and silt. Altered Envirogel (sample 16) was prepared by previous reaction for 6 days at 250 °C, water/bentonite ratio = 0.15.

* Includes (8 ± 4)% initial water content of bentonite, except for sample 5, which was heated dry in an open vessel.

† Water and bentonite mixed ultrasonically before heating. Sample absorbed all water to form a gel, and remained gelled after hydrothermal treatment.

Table 2 Alteration of bentonite at controlled P_{H_2O}

Bentonite	Temperature (°C)	P_{H_2O} (MPa)	Relative humidity (%)	Swelling capacity ($\text{cm}^3 \text{g}^{-1}$)
Envirogel	250	3.7	93 ± 2	10 ± 1
Envirogel	Unaltered	—	—	37 ± 4

Bentonite was heated to 250 °C in a vessel at atmospheric pressure, the vessel was evacuated, water vapour introduced at $P_{H_2O} = 3.7$ MPa, the pressure was maintained for 18 h, and then the pressure was released, the bentonite was cooled to room temperature and the swelling capacity was determined. Liquid water was never present during alteration; the maximum P_{H_2O} was $93 \pm 2\%$ of saturation. (The temperature was controlled by a mechanical convection oven to a precision of better than ± 0.1 °C. P_{H_2O} as a percentage of saturation pressure was measured with a high-precision transducer and was verified by measuring the vapour pressure of pure water at 250 °C.)

(sample 6). Reaction with basaltic groundwater has the same effect as reaction with pure water (samples 10, 11), because the concentration of solutes in the water is insignificant compared with the concentration of soluble impurities and exchangeable ions in the bentonite.

Measurements of vapour pressure and water content of bentonite (unpublished work) have shown that the water is partitioned between water of hydration and vapour. Liquid water did not coexist with these samples at 250 °C.

To clarify the effects of liquid, vapour and water of hydration on bentonite, two experiments were performed, one in which liquid water was always absent and one in which liquid water was always present (to form a gel). In the first experiment, the bentonite was altered isothermally at a controlled partial pressure of water, 93% of saturation. Table 2 gives methods and results. The great reduction in swelling capacity shows that water of hydration and/or vapour was responsible for alteration. In the second experiment, water and bentonite were mixed in a ratio of 20:1 to form a gel. After reaction (samples 14 and 15, Table 1), the samples remained gelled, showing little or no loss of swelling capacity. Thus, reaction with water vapour, but apparently not with liquid, causes rapid, severe loss of swelling capacity.

The maximum alteration took place at water/clay ratios of roughly 0.15–0.25 at 250 °C (Table 1). This corresponds approximately to one to three absorbed water layers per 10-Å silicate layer in the montmorillonite structure (with allowance for up to 0.12 g water vapour in the autoclaves). Evidently, some water is necessary for the alteration, but alteration is slow or does not

Fig. 1 X-ray diffraction of purified montmorillonite (Envirogel), unaltered (top) and altered (sample 12, bottom). Relative humidity controlled at 33% with saturated solution of $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. Basal spacings: 12.4 Å unaltered, 12.5 Å altered, determined from four basal reflections. Complete conversion to the calcium form would shift the spacing to 15.4 Å, at $5.7^\circ 2\theta$ (ref. 18). $\text{CuK}\alpha$ radiation, General Electric diffractometer, slits: 1° entrance, medium resolution divergence, 0.2° receiving, $2^\circ 2\theta \text{ min}^{-1}$, time constant 2 s

take place in dilute systems, with low concentrations in the hydrated layers.

To determine whether the effect is reversible on contact with liquid groundwater, altered bentonite was reacted with a large excess of liquid groundwater. The swelling capacity of the product (sample 16) remained low. Therefore, the effect is not reversible over the timescale of the test.

The alteration is temperature-dependent, as shown by experiments at 250 °C, 200 °C and 150 °C (samples 9, 17 and 18). A large effect was observed as low as 150 °C.

The reduced swelling capacity corresponds to reduced uptake of water by hydrated layers of the montmorillonite structure. Unaltered montmorillonite expands greatly, in some cases from an average basal spacing of 10 Å in the dry state to over 100 Å in water^{2,15,16}. However, montmorillonite altered by water vapour at 250 °C expands only to a maximum basal spacing of 19 Å, which corresponds to three water layers per 10 Å silicate layer in the structure.

Except for the change in swelling behaviour, relatively little mineralogical change was observed. Both the altered and unaltered bentonite consist mainly of a dioctahedral smectite with an X-ray diffraction peak at 1.50 Å, and a basal spacing of 17 Å when treated with ethylene glycol. The reacted sample show evidence of slight uptake of exchangeable calcium from calcite, as shown by energy dispersive analysis in the scanning electron microscope (SEM) and as suggested by a small X-ray reflection at ~ 14.7 Å (at 33% relative humidity). However, a sample which was purified by sedimentation before reaction showed a similar reduction in swelling capacity (sample 12, Table 1) but much less uptake of calcium, as determined by analyses for exchangeable Na and Ca (Table 3), by analysis of single particles in the SEM, and as suggested by X-ray diffraction at controlled humidity (Fig. 1). Evidently, the change in swelling behaviour is not due to extensive exchange of calcium for sodium. Alteration was accompanied by significant fixation of magnesium (Table 3), but it is questionable whether the rather small amount of magnesium can account for the change in behaviour.

The mechanism has not been determined, but it may be due to hydrolysis of exchangeable cations, to an attack on the octahedral layer, with release of aluminium into interlayer positions, or to oxidation of ferrous iron.

The alteration was apparently not due to reaction with the vessel materials. No reaction rim was observed, and minimal swelling capacity was observed after reaction in either stainless steel or Inconel vessels. Furthermore, no uptake of Ni or Cr was detected by elemental analysis in the SEM.

The observed rapid change in montmorillonite properties has important implications for the use of bentonite at high temperatures. If bentonite is exposed to moisture at temperatures

Table 3 Exchangeable ions in bentonite (mmol g^{-1}) before and after alteration

	Na (method 1)	Ca (method 1)	Ca (method 2)	Mg (method 4)
Untreated (purified Envirogel)	0.56	0.16	0.11	0.05
Treated (sample 12)	0.51	0.13	0.12	0.01

Method 1: Determined by leaching overnight with 1 M NH_4Cl . Solutions were analysed by inductively coupled plasma atomic emission spectroscopy (ICP). Analytical accuracy $\sim \pm 5\%$. Partial dissolution of calcite may increase Ca analyses. Method 2: Determined by washing with 60% ethanol in water (by volume) and then leaching with 0.5 M LiCl, 0.5 M CsCl solution in 60% ethanol (after Neal)¹⁷. Samples (0.15–0.21 g) were rinsed twice for 15 min each with 60% ethanol, leached for 12 h with LiCl, CsCl solution, washed with 10 ml ethanol/water, leached for 2 h with 10 ml LiCl, CsCl solution, washed with 10 ml ethanol/water, then 5 ml. Samples were centrifuged after each washing or leaching. Leach solutions were combined and analysed by ICP. All solutions were de-aerated and kept under N_2 before use. This method is reported to dissolve insignificant amounts of calcite¹⁷. Analytical accuracy $\pm 5\%$.

of 250 °C or higher, the permeability⁷ and the ability to swell and fill fractures will be greatly decreased. The effects observed here need to be addressed for safe design of nuclear waste repositories, and additional work on the mechanism of alteration may be required. Reduction of the swelling capacity also occurs at 150 °C and may occur at still lower temperatures, especially after long time periods. Bentonite used to fill tunnels and drifts in nuclear waste repositories may reach high enough temperatures to be adversely affected by water vapour.

This work was supported by the US Nuclear Regulatory Commission. I thank D. Alexander and K. Kim for enthusiastic support of the project; D. Eberl, M. Kastner and C. Neal for discussions on mineralogy and chemistry; T. Abrajano, D. Eberl, M. Kastner, M. Seitz, M. Steindler and N. Sturchio for comments on the manuscript; R. Bane, E. Huff and B. Tani for laboratory work; and Wyo-Ben, Inc. and the Baroid Corporation for supplying samples.

Spin-dependent electron scattering from optically active molecules

D. M. Campbell & P. S. Farago

Department of Physics, University of Edinburgh,
Edinburgh EH9 3JZ, UK

The origin of the isomeric purity of biomolecules has been extensively discussed¹. In particular, it has been suggested that spin-polarized electrons or positrons emerging in the β -decay of radioactive nuclei may have led to a preferential destruction of one of the two isomers at an early stage of evolution and that this process tipped the initial balance of abundance of the two self-replicating isomers². As experimental tests of this hypothesis have remained largely inconclusive^{3,4}, it seemed useful to investigate the spin dependence of electron scattering from optically active molecules under the simplest possible conditions. Here we describe an experiment which indicates that spin-polarized electrons, like polarized light, when scattered from optically active molecules, can 'distinguish' between right-handed and left-handed isomers.

The application of fundamental conservation principles has shown that the 'handedness' of target molecules leads to spin-

Fig. 1 Measurements of the electron polarization and beam attenuation with and without camphor and alternating the load in the target cell between the D(+) and L(-), respectively. Those obtained with camphor using polarized incident beams ($P = 0.28 \pm 0.02$) are marked D(+) and L(-), respectively. The remaining points were obtained with unpolarized incident beams ($P < 0.005$) or without camphor. The error bars indicate 1 s.e. The results obtained with unpolarized electrons or without camphor were also combined. The standard error of their weighted mean defines the hatched belt between the broken lines.

dependent scattering phenomena that are completely analogous to optical activity and circular dichroism⁵. Our objective here was to measure the attenuation of longitudinally polarized electron beams passing through a vapour of optically active molecules. This attenuation can be calculated in terms of two elastic forward-scattering amplitudes, one spin-independent, f , and the other chirality-dependent, h . The sign of h changes with the handedness of the molecules; $h = 0$ for non-chiral molecules. If I_0 is the incident beam intensity, P its longitudinal polarization, ρ the vapour density, z the path length, and the electrons undergo single scattering only, then the transmitted intensity is

$$I = I_0 \exp(-q\rho z) [\cosh(q\rho z X) - P \sinh(q\rho z X)] \quad (1)$$

where $q = (4\pi/k) \text{Im}(f)$ is the total spin-independent scattering cross-section and $X = \text{Im}(h)/\text{Im}(f)$. X measures the chirality-dependent cross-section in units of the spin-independent one, I_m denotes the imaginary part and k is the electron wave number.

If the transmitted intensity is measured for a pure isomer at a given target density and a given electron polarization, alternately parallel and antiparallel to the beam axis, the two output intensities, $I(P)$ and $I(-P)$, yield an intensity asymmetry,

$$A(P) = [I(P) - I(-P)]/[I(P) + I(-P)] \\ = -P \tanh(q\rho z X) = -P q \rho z X \quad (2)$$

to first-order approximation.

Thus, the following predictions can be made. (1) For a given isomer at a fixed magnitude of the longitudinal electron polarization, the magnitude of the asymmetry increases linearly with the sample density. (2) The asymmetry changes sign if the handedness of the sample is reversed. (3) The asymmetry vanishes if either the electron beam is unpolarized or the sample is a racemic mixture.

The first experiment, designed on the grounds of general symmetry considerations and using D(+)-camphor molecules as target and 25 eV initially unpolarized electrons, remained inconclusive in that it could establish only an upper limit to the in-plane polarization of the scattered electron⁶. Gidley *et al.*⁷ investigated asymmetrical positronium formation in optically

active molecules using slow spin-polarized positrons and found a positive effect in one case but none in two others.

The apparatus used in the present experiment consists of three stages: a GaAs polarized electron source⁸, an electron polarimeter used in a transmission mode to monitor the incident beam intensity and electron polarization⁹, and an electron spectrometer, adapted from the scheme introduced by Simpson¹⁰. The scattering target was camphor vapour at room temperature, and the experiment was carried out at 5 eV energy. Simultaneous measurements of the electron polarization and beam attenuation consisted of 'runs' taken in turn with and without camphor and alternating the load in the target cell between the D(+) and L(-) isomer, respectively. The results displayed in Fig. 1 were obtained by combining the results of corresponding runs.

Figure 1 shows, first, that in the absence of camphor and in the case of unpolarized incident electrons the observed asymmetry vanishes and, second, that for the two isomers, when electrons beams of the same polarization are used, the asymmetry is of different sign. The measured values are different from zero by 2 s.e. or more; the magnitudes of the asymmetries agree within their error margin. Thus, we conclude that the results confirm the existence of an 'electron optic dichroism' with a confidence limit exceeding 95%.

The experimental results allow a tentative estimate of the ratio $Im(h)/Im(f)$. In typical working conditions, camphor in the sample cell attenuated the beam by a factor of 4–5. As our equipment could not give an absolute measurement of the sample pressure, only relatively crude tests were performed to see that up to this level of attenuation single scattering conditions prevailed. Thus, from equation (2)

$$A = -P \ln(I_0/I) \quad Im(h)/Im(f)$$

and hence, with the measured values $P = 0.28$, $4 < I_0/I < 5$ and $A > 10^{-3}$, one finds

$$X = Im(h)/Im(f) > 2 \times 10^{-3}$$

The mechanism of the interaction involved is unknown. There are no theoretical estimates of X , although there are estimates of the related quantity $Re(h/f)$, where Re denotes the real part. Based on the 'helicity density' model, Rich *et al.*¹¹ estimated for camphor at low electron energy $Re(h/f) \sim 10^{-5}$. Hayashi¹² calculated the in-plane component of the spin polarization of initially unpolarized electrons scattered elastically by optically active molecules (1,3-dimethylallene) at 50 eV and above: $Re(h/f) < 5 \times 10^{-7}$.

We stress that the ratio X can be significantly different from $Re(h/f)$. More importantly, neither of the theoretical calculations quoted takes account of possible resonance scattering, which may increase the effect by orders of magnitude. At the energy at which the present experiment was conducted (5 eV), the possibility of resonance effects cannot be ruled out. It is suggestive that the optical absorption of photons about this energy certainly involves pronounced broad resonance^{13,14}.

We acknowledge the contributions made by R. Owen and M. Veitch to the development of the apparatus, its testing and the early stages of the measurements. P.S.F. thanks L. Keszthelyi for conversations which called his attention to this subject.

A small coleoid cephalopod with soft parts from the Lower Devonian discovered using radiography

W. Stürmer

Private Research Laboratory for Interdisciplinary Palaeontology, Burgbergstrasse 20, D-8520 Erlangen, FRG

During the past 50 years, X-ray examinations have greatly increased our knowledge of fossils. Modern radiographic methods, X-ray tubes with fine focal spots, high-resolution films and optimal exposure conditions have revealed details of the anatomy and general biology of ancient life as well as species and representatives of major groups hitherto unknown in the Lower Devonian^{1–5}. Most of this material came from the Hunsrück slate, where most fossils are converted to pyrite, FeS₂, giving a good contrast in the radiographs. Additional image processing may reveal even more details. While screening large quantities of black slate pieces, I have discovered a small teuthid coleoid showing soft parts (Fig. 1) which is the best-preserved specimen I have found during 20 years of investigation. This *Eoteuthis elfriedae* n.sp. is very similar to the living *Alloteuthis africana* of the Loliginidae, and is one of many unusual fossils yielded by this slate^{3–5}, only a few of which have been published. This specimen of *E. elfriedae* shows that *Alloteuthis*-like animals have not changed much over the past 400 Myr, and means that previous concepts of the appearance of such forms must be revised.

More than 100 gladii and cuttle bones of other teuthid coleoids have been recovered in the past 2 years from the Kaisergrube, an old mine near Gemünden in the Hunsrück. They all show a typical growth striation, but radiography reveals that none of them has soft parts. Similar striation has been observed⁶ in the

Fig. 1 a, Extant *Alloteuthis africana* (Gulf of Guinea, R/V Geromino Sta 2-730680, Smithsonian Institution). b, Radiograph of *A. africana* (Gulf of Guinea, R/V Geromino Sta 2-1910 from 730680, Smithsonian Institution). c, Radiograph of the Lower Devonian teuthid of the Black Slate of Bundenbach/Hunsrück, FRG (WS 3023). Scale bars, 10 mm. The radiographs were made with a Siemens Kristalloflex II unit in combination with a special water-cooled fine focus tube. The Agfa Millimask plates were used as photographic material which allow observation of details down to <5 μm. Intermediate negatives with enhanced detail contrast were made using a TV-microscope in combination with a Siemens Transicon image processing unit.

Fig. 2 The head of *Eoteuthis* showing the tentacles. The series of pyrite dots is visible. The jaw can be seen in the lower half. Scale bar, 10 mm.

Table 1 Description of *Eoteuthis elfriedae* n.sp.

Class	Cephalopoda
Subclass	Coleoidea BATHER 1888
Order	Teutkida NAEF 1916
Family	Loliginidae <i>sensu stricto</i> Steenstrup 1861. As only one specimen exists, the characterization of the genus must be the same as that of the species.
Species*	<i>Eoteuthis elfriedae</i> n. sp.
Holotype	Bavarian State Coll. Munich, No. 1984 I 100 (Radiographs: WS 3023); specimen showing soft parts on radiographs (Fig. 1)
Locality	Black slate mine Herrstein, Bundenbach, Hunsrück (FRG)

* The species is named in honour of Mrs Elfriede Stürmer, whose enthusiastic efforts have revealed hundreds of Lower Devonian coleoid cephalopod remains.

Fig. 3 The jaw of *Eoteuthis* after image processing: j, jaw; e, oesophagus; r, radula (?). Scale bar, 1 mm.

Fig. 4 The fin of *Eoteuthis* with concave posterior border after electronic image processing. Scale bar, 10 mm.

fragmental prebelemnites, *Hyolithoconularia striata* found in the Lower Devonian of Morocco. A detailed account on the Hunsrück material will be published elsewhere.

The preservation of the soft part of a fossil is unusual but the Hunsrück slate contained favourable conditions for preservation^{4,5}: the organic sulphur compounds of the animal (or of sulphur bacteria) form pyrite, FeS₂, in the presence of iron ions in the interstitial water of the sediment. This pyrite is opaque

to X rays, so even a thin veil of FeS₂ at optimal exposure conditions produces a good contrast in the radiograph^{4,5}.

The body organization of this little teuthid, *E. elfriedae*, resembles that of the living *Alloteuthis* (Table 1) and seems to indicate that this type of cephalopod existed in the Lower Devonian. It is a good example of long survival in the fossil record.

This small teuthid cephalopod is similar to the extant *A.*

africana, with some well-preserved soft parts. There are eight or nine visible arms/tentacles, not definable in detail; the jaw is partly visible in the radiograph (Fig. 2) together with a fin which has a concave posterior border (Fig. 4). The total length of *E. elfriedae* is 83 mm, its maximum width 9 mm. The specimen is flat and has an estimated thickness of <0.5 mm; the original diameter of the more or less tubiform animal may have been ~6 mm. Some of the arms/tentacles have rows of little spots (suckers?) (Fig. 2). The jaws are visible just behind the tentacle bases (Fig. 3). The oesophagus seems to be below the tip of the beak (Fig. 3, e). To the left, between the beak and oesophagus are three rows of faint regular dots which may represent the radula (Fig. 3, r). One of a pair of lateral fins (Fig. 4) has a concave posterior border, as in the extant *Alloteuthis*⁷. The opposite fin is directly attached to the body and is thus invisible in the radiograph. Owing to the heavy pyritization of the body the gladius cannot be reconstructed. We must assume that the animal was buried very rapidly which prevented bacterial dissolution of the soft structures. Also, compaction must have taken place at an early state of diagenesis, flattening the body and the soft parts to <0.5 mm. The distortion of the soft parts as a result of this compaction makes it difficult to compare with living *Alloteuthis*-like animals. The process of pyritization is not fully understood. Observations on slate pieces from the Kaisergrube reveal hundreds of small cephalopods and tentaculites on one slab, and several states of FeS₂ exist side by side. My experiments on the fossilization process in the laboratory by putting *Cirolana* specimens from South Norway into different metal salt solutions produced a surprising result: radiographs made at 6-weekly intervals for the first year, then at 6-monthly intervals, show a 'fossilization' that remains constant after the first 6 weeks, so the experiment was concluded after 4 yr.

There are many tables⁸⁻¹² illustrating the ancestry of cephalopods, but because some points in such evolution charts are based on only a few moderately well preserved fossil specimens, only general statements should be made until we know more about fossil and modern gladii (see ref. 13 for a critical analysis). Table 2 shows that a fully developed octopus, *Proteroctopus tibeti*¹, existed in the Jurassic; Johnson and Richardson² found a 10-armed cephalopod *Jeletzkyia douglassae*, in the Mazon Creek fauna from the Middle Pennsylvanian of Illinois. Radiography clearly reveals the complete tentacular crown and fragile shell of this unique fossil. Double rows of hooks on the arms are well preserved. *E. elfriedae* is a highly developed teuthid of the Lower Devonian, and the ectocochleate nautiloids go back to the Cambrian¹⁴. If we consider the timescale and the fact that the fossil record shows few closely related forms, then more questions arise, especially as to the origin of these animals. How long did it take to evolve from a primitive nautiloid to *Eoteuthis*, and where might one hope to find connecting forms?

I thank Professor G. L. Voss for the first hint that the fossil may be an *Alloteuthis* and for helpful discussions. Financial support for the Hunsrück research by the Volkswagen Foundation and the German Research Society is acknowledged. I also thank Dr C. F. Roper and Dr Jeletzky, for many discussions; and especially Dr C. F. E. Roper for specimens of extant *Alloteuthis* animals for comparison radiographs.

Biogenic fluxes of carbon and oxygen in the ocean

Trevor Platt & William G. Harrison

Marine Ecology Laboratory, Bedford Institute of Oceanography, PO Box 1006, Dartmouth, Nova Scotia, Canada B2Y 4A2

Rates of oxygen utilization (OUR) at depth in the ocean have been interpreted as showing that rates of carbon fixation by phytoplankton, as estimated by ¹⁴CO₂ assimilation *in vitro*, must be in error¹. The oxygen is consumed in the decomposition of organic matter sinking from the photic zone: there is a stoichiometrically equivalent flux of nitrate from the deep water towards the surface². For comparison with the ¹⁴C data, it is conventional to extrapolate OUR to total equivalent phytoplankton production through a constant factor *f*, the ratio of nitrate-based production (*P*_{new}) to total production (*P*_t) as defined by Dugdale and Goering³. The alternative hypothesis, that scaling up OUR by a constant factor *f* is inappropriate, has not been examined in detail. We show here that *f* is variable in space and time for most provinces of the ocean. Furthermore, we show that in nitrogen-limited systems, such as the pelagic of the open ocean, *P*_t and *f* should be positively correlated. Applying these results to data from the Sargasso Sea, we find that the carbon fluxes estimated by ¹⁴C assimilation are consistent with the oxygen fluxes estimated by OUR. The conclusion is of profound importance for understanding the major biogeochemical cycles of the ocean.

Alternative methods for measuring the same ecological rate do not necessarily refer to the same time-scale. Accumulation of oxygen in the photic zone of the ocean⁴ or its consumption at depth^{1,5} provide estimates of phytoplankton production with a characteristic timescale of months to years. Measurements of carbon fixation by *in vitro* incubation have a characteristic time-scale of the same order as the incubation time, ≤24 h. We have pointed out^{6,7} that extreme caution should be taken when comparing data sets whose intrinsic timescales are not compatible. The one has to be averaged to conform with the other, and we usually have little information on which to base the averaging in time. Moreover, OUR calculations imply some averaging over depth, whereas ¹⁴CO₂ assimilation is measured at discrete depths.

For an arbitrary depth stratum, one need not necessarily expect that the carbon and oxygen fluxes will balance when averaged over some arbitrary time interval. Within the variance between years (which can be appreciable⁸), the natural biological timescale at which the carbon and oxygen fluxes can be expected to balance is the annual one. One of the very few

Fig. 1 Relationship between *f* and ambient NO₃⁻ concentration using the depth profile data of ref. 25 and the seasonal data of ref. 26. Data for which ambient NH₄⁺ concentrations exceeded 0.1 μg atoms l⁻¹ were omitted. Data fitted to an exponential model: $f = f_{\max}(1 - e^{-(\alpha \text{NO}_3^-/f_{\max})})$, for which $f_{\max} = 0.83 \pm 0.08$ and $\alpha = 5.48 \pm 0.77$.

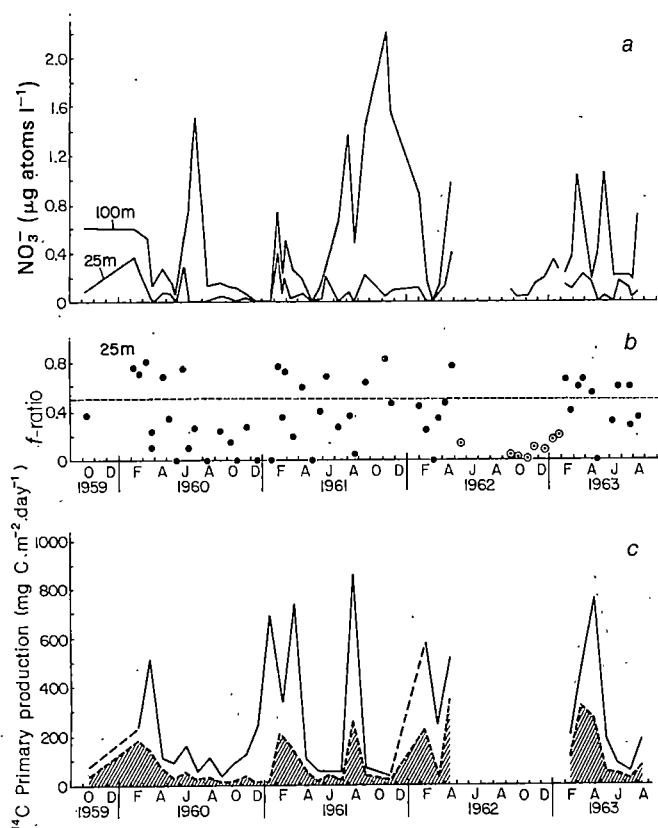

Fig. 2 Time-series data of: *a*, ambient NO_3^- concentrations; *b*, f computed from the model given in Fig. 1; and *c*, total ^{14}C , and new primary production (P_{new}) at station S, Bermuda; integrated 0–100 m. New production (P_{new}) estimated as fP_T where P_T is assumed to be equivalent to ^{14}C results. In *b* \odot are f values determined directly from ^{15}N measurements (ref. 3): these data appear to be fully consistent with the trends shown by the indirectly determined values of f .

oceanic data sets having anywhere near sufficient resolution in time that reliable annual means of primary production and OUR can be calculated is that from station S in the Sargasso Sea⁸. From these data, Jenkins and Goldman⁵ compute an OUR at depth of the order of $5 \text{ mol m}^{-2} \text{ yr}^{-1}$. We now consider how this estimate of new production should be scaled up to give total production.

The conventional procedure¹ is to apply to the annual new production a constant factor $\bar{f} \approx 0.05$ said to be characteristic of oligotrophic ocean water². An alternative procedure, adopted here, is to estimate $f(z, t)$ for each depth z for all times t during the year.

Normally f is estimated from measurements of the *in vitro* assimilation rates of $^{15}\text{NO}_3^-$ and $^{15}\text{NH}_4^+$. There are very few such data for the Sargasso Sea. However, provided the concentration of ammonia is low, $\leq 0.1 \mu\text{M}$, such that neither the uptake of nitrate nor its enzymatic reduction are suppressed, f can be related to ambient nitrate concentration (Fig. 1). We use this dependence to estimate $f(z, t)$ from the nitrate concentrations reported at station S (Fig. 2). It is found that f is not constant, but varies between 0 and 0.84.

We now state an important inequality for nitrogen-limited systems:

$$\iint f(z, t) P_T(z, t) dz dt \geq \bar{f} \iint P_T(z, t) dz dt \quad (1)$$

where

$$\bar{f} = \frac{\iint f(z, t) dz dt}{\iint dz dt}$$

In other words, P_{new} estimated by the weighted integral on the left-hand side of equation (1) will always exceed P_{new} estimated

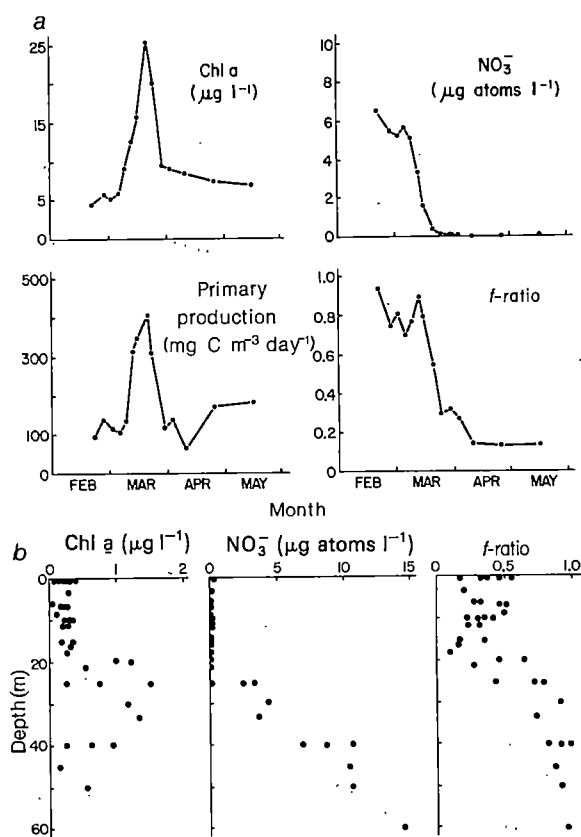

Fig. 3 Relationship between f and ambient NO_3^- concentration: *a*, during the decline of the spring phytoplankton bloom in a temperate coastal embayment (Bedford Basin, Nova Scotia); and *b*, in depth profiles on the continental shelf of the middle Atlantic Bight in summer. Here, f is derived directly from $^{15}\text{NO}_3^-$ and $^{15}\text{NH}_4^+$ uptake measurements.

by the right-hand side, mean value approximation. This is because $P_i(z, t)$ and $f(z, t)$ will have a finite (positive) covariance where nitrogen is the limiting resource. That is, a local pulse in available nitrate will result in a local increase in f at the same time²⁷ as it increases the local magnitude of P_i (Figs 2, 3).

Applying the weighted integral to the ^{14}C data for station S, one finds that, on an annual basis, new production is 31% of total production (Table 1). The ^{14}C data show an average production of $6.8 \pm 1.9 \text{ mol C m}^{-2} \text{ yr}^{-1}$, separable now into $2.1 \pm 0.58 \text{ mol C m}^{-2} \text{ yr}^{-1}$ of new production and $4.7 \pm 1.3 \text{ mol C m}^{-2} \text{ yr}^{-1}$ regenerated production ($P_T - P_{\text{new}}$). Applying photosynthetic quotients of 1.8 to the new production and 1.25 to the rest⁹, we find the oxygen equivalent of the ^{14}C results to be $9.7 \pm 1.9 \text{ mol O}_2 \text{ m}^{-2} \text{ yr}^{-1}$, of which $3.8 \pm 1.0 \text{ mol O}_2$ is new production. Jenkins and Goldman⁵ found an OUR at depth to be in the range $4.1\text{--}5.9 \text{ mol O}_2 \text{ m}^{-2} \text{ yr}^{-1}$ depending on the corrections applied for diffusive losses and abyssal respiration. It does not appear, therefore, that there is any significant difference between the two independent indices of new production. And we certainly do not find that the respiration at depth (P_{new}) exceeds the primary production at the surface (P_T), as was claimed for the subtropical gyre of the North Atlantic, and interpreted as showing that the ^{14}C results must be in error¹.

In fact, adopting a small and constant \bar{f} when P_{new} is as high as $5 \text{ mol O}_2 \text{ m}^{-2} \text{ yr}^{-1}$ leads to a contradiction in Fig. 2a of ref. 2, for then the implied estimate of P_T is $\approx 100 \text{ mol O}_2 \text{ m}^{-2} \text{ yr}^{-1}$, which would require an asymptotically high value for \bar{f} (≈ 0.5). We have shown that the contradiction stems from an improper selection of \bar{f} rather than from a discrepancy between the ^{14}C results and the true values of total production. Indeed, putting the effective annual $\bar{f} = 0.31$ as calculated here into equation (1) of ref. 2 yields $P_T = 124 \text{ g C m}^{-2} \text{ yr}^{-1}$, not grossly at variance with the mean annual ^{14}C value of $82 \pm 23 \text{ g C m}^{-2} \text{ yr}^{-1}$ (Table

Table 1 Mean monthly and annual ^{14}C primary production rates from Station S, 1959–63

Month	Primary production (g C per m ² per month)		
	P_T	P_{new}^*	f
1	12.2 (12.4)	1.2 (1.5)	0.10
2	10.2 (5.1)	5.4 (1.6)	0.53
3	14.9 (6.1)	4.8 (3.4)	0.32
4	11.3 (9.7)	5.5 (4.4)	0.49
5	3.3 (2.2)	0.8 (0.6)	0.24
6	2.8 (1.5)	1.2 (0.3)	0.43
7	1.7 (0.1)	0.6 (0.1)	0.35
8	11.8 (12.5)	3.5 (3.6)	0.30
9	1.6 (0.5)	0.7 (0.5)	0.44
10	2.5 (0.4)	0.6 (0.4)	0.24
11	2.3 (1.8)	0.7 (0.3)	0.30
12	7.5 (4.4)†	0.2 (0.1)†	0.03
Annual	82.1 (22.2)‡	25.3 (7.0)‡	0.31§

Monthly rate = mean daily rate $\times 30$. Data are given ± 1 s.d.

* $P_{\text{new}} = \int P_{\text{new}}(z, t) dz$ averaged for the month, where $P_{\text{new}}(z, t) = P_T(z, t) \times f(z, t)$.

† Variance estimated.

‡ The measures of dispersion given are ± 1 s.d. of the annual totals computed on the basis of the standard deviations of the monthly averages; they are not intended to be explicit statements of the confidence intervals at any particular probability level.

§ Annual P_{new} divided by annual P_T . Annual figures are based on some 51 sampling dates.

1). Note also that these two values are quite independent of each other.

Another problem with the extrapolation of high values of total production through division of new production by a small value of f is that the implied efficiency of photosynthesis is too great to accept. It can be shown that extrapolation of the OUR estimates of P_{new} to P_T through application of an f ratio ≈ 0.5 is equivalent to a photosynthetic efficiency $\geq 6\%$, a value too high to be believable as an annual average¹⁰.

Evidence is accumulating that the distributions of biological properties in the ocean are highly variable in space and time. We conclude this from sediment trap data¹¹; from satellite data¹²; from samplers deployed from a moving ship¹³; from theoretical physical oceanography¹⁴; and from theoretical ecology¹⁵. Superimposed on this variance in the Sargasso Sea is a strong seasonal cycle in both primary production and nutrient availability¹⁶; for example, the four months January–April account for $\approx 60\%$ of the annual assimilation of $^{14}\text{CO}_2$ (Fig. 4).

It therefore becomes increasingly untenable to speak about a particular ocean province, and certainly not the Sargasso Sea, as being 'oligotrophic'. Rather, a given oceanic province can be expected, locally in $(x, y, z \text{ and } t)$, to manifest a range of characteristics from apparent extreme oligotrophy to eutrophy. For example, judging by the f ratio alone, a temperate, coastal embayment can appear to change its trophic status from eutrophic to one characteristic of the open-ocean stereotype within the space of a few weeks, if a sufficiently detailed time-series is available (Fig. 3a). Local or transient fluctuations away from oligotrophy will account for a high proportion of the annual primary production. Moreover, most of the production in these events will be new production. The effective f ratio for the year (proportion of the total annual carbon fixation that is based on nitrate) will, therefore, be much higher than has previously been supposed.

The open ocean is still heavily undersampled with respect to primary production. For example, the water column primary production rates for Station S have to be computed from data collected at only three depths. In the open ocean, the distribution of phytoplankton is highly non-uniform in depth¹⁷, and the existence almost everywhere in the ocean of a deep chlorophyll maxima is well established¹⁸. If more sampling depths were

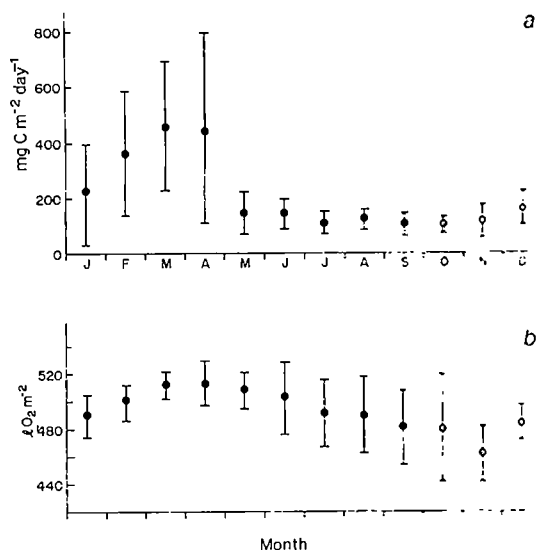

Fig. 4 Long-term averages (± 1 s.d.) of ^{14}C primary production (a) and dissolved O_2 (b) concentrations at Station S, Bermuda. These values represent a longer time-series (1957–63) than those shown in Fig. 2.

available, the estimate of depth-integrated production would probably increase. A similar tendency for the mean rates to increase can be expected as the resolution of sampling is improved in time and in the (x, y) plane.

We conclude that in a nitrogen-limited ocean ecosystem, local events (positive anomalies) in the nitrate field account for a disproportionately high fraction of the annual signal in primary production. During these events, the margin between new and total production narrows. On the other hand, the factor converting carbon fixation to oxygen evolution is at its highest. Taken together, these points are sufficient to show that the available flux data for carbon and oxygen in the Sargasso Sea are not internally inconsistent. It is one more example of the crucial importance of giving at least as much emphasis to the variances as to the means in discussing the dynamics of nonlinearly coupled systems¹⁹. The implied picture of the pelagic ecosystem (intermittent nitrate supply; new production one-third of total) is at variance with that presented by Goldman²⁰ where production is controlled by 'oases of regeneration' associated with particulate aggregates, and where 'spinning wheel' metaphor characterizes the supposed, rapid rate of nutrient recycling.

These conclusions are of importance not only for our understanding of the pelagic ecosystem but also for incorporation into budget calculations for the great biogeochemical cycles of the ocean^{21,22}. The conclusions have a direct bearing on current discussions of the possible role of the ocean biota as a control on the concentration of CO_2 in the atmosphere, and thus bear indirectly on the prediction of the future climate of the Earth^{23,24}.

We thank Drs P. Brewer, W. Broecker, A. Clarke, J. Cullen, D. Cushing, W. Jenkins, G. Knauer, M. Lewis, A. Longhurst, K. Mann and J. Sarmiento for comments.

A structurally preserved magnolialean fructification from the mid-Cretaceous of Japan

Harufumi Nishida

International Budo University, 841 Monomizuka, Shinkan, Katsuura, Chiba Prefecture, 299-52 Japan

Fossil evidence throwing light on the origin and diversification of angiosperms (flowering plants) has been increasing rapidly over the past 10 years. Most palaeobotanists accept that angiosperms first diversified in the Barremian stage of the Cretaceous, but this is based mainly on strato-phenetic morphological studies of palynomorphs and vegetative organs¹⁻³. Reproductive organs such as flowers and fructifications, which are vital to a full understanding of angiosperm evolution, are rare and have only recently been described in any detail from Cretaceous rocks⁴⁻¹¹, and even these are generally preserved as compressions or as fusinized remains. Here I report a permineralized angiosperm floral axis bearing conduplicate carpels from mid-Cretaceous sediments of Hokkaido, Japan. Its structure most closely resembles that of extant Monimiaceae and Austrobaileyaceae of the Magnoliales, particularly in the concave receptacle, but it shows several features considered more primitive than those occurring in any extant family. The fossil extends and clarifies knowledge of the structure and evolution of early angiosperms and is the first report of a permineralized angiosperm fructification of Cretaceous age.

The fructification was collected by Mr Masaharu Kasai in a tributary of the Sankebetsu River, Haboro district of Hokkaido, in Cretaceous shallow marine sediments of the Upper Yezo Group. The ammonite *Mesopuzosia pacifica* Matsumoto in the same calcareous nodule indicates a Turonian age.

The specimen has a woody peduncle, 25 mm long and 4 mm in diameter, with an attached globose floral structure ~25 mm in diameter (Fig. 1a). The floral structure is composed of many foliicles (Figs 1b, 2), and reconstruction (Fig. 2b) illustrates that

Fig. 1 a, Side view of the fossil fructification showing attachment to a long peduncle. Scale in cm. b, Longitudinal section showing concave receptacle and falcate foliicles containing ovules. Follicles from right to left correspond to those in Fig. 2b between the two parallel lines and numbered 18, 11, 6, 4, 2 and 3. Scale bar, 0.5 cm.

Fig. 2 Cross-sections of the fructification. The upper part of the figure corresponds to the surface shown in Fig. 1. a, Section of the specimen corresponding to the left half of b. b, Diagrammatic reconstruction of foliicle arrangement. Numbers show pairs of foliicles in a helically decussate arrangement. Scale bars, 0.5 cm.

the arrangement of the foliicles is intermediate between decussate and helical.

The median longitudinal section in Fig. 1b shows that the foliicles were borne on a concave receptacle. Each foliicle is 17 mm long × 3.1 mm wide and falcate, curved slightly towards the adaxial surface. They are sessile or have a short stalk and taper towards their apices. An adaxial longitudinal slit starts 1 mm from the base of each foliicle and runs nearly to the apex. A pair of marginal ribs occurs alongside this slit, bearing abundant unicellular, simple trichomes (Fig. 3). The slit evidently represents the stigmatic crest of a conduplicate carpel. Paracytic stomata occur on the external wall of the foliicle.

In the foliicle a pair of adaxial veins passes through the marginal ribs along the stigmatic crest. An abaxial vein runs right up to the apex of the foliicle, producing an unknown number of lateral bundles, and then curves to the adaxial surface, where it ends blindly about 0.5 mm below the point of incurving.

Most of the receptacle is infilled with sandstone matrix, but its base is preserved and shows many bi-collateral bundles arranged in a ring. There is no direct evidence that stamens or petals were attached, but bundles occur at the base of the receptacle which do not enter foliicles and are directed to the receptacle periphery. These may represent traces to stamens or perianths.

There are at most 15 ovules per foliicle attached alternately along the adaxial stigmatic crest, and therefore having marginal placentation. The funicles are short and the ovules bitegmic (Figs 3, 4). The outer integument comprises a thick, sclerotic outer layer and a thin inner one which develops a thick parenchymatous cushion around the micropyle. The inner integument is only one cell thick and is generally very thin, but the cells surrounding the micropyle are elongated radially, making the layer thicker.

A globose structure of unknown function is present between the micropyle and funicle (Fig. 4a). It seems to be some kind of aril, but further discussion is precluded at present because so little is known about the ovuliferous structures of comparable living angiosperms. No palynomorphs were recovered.

Secondary xylem is well developed at the base of the peduncle, and mucilage cells surrounded by epithelial cells are abundant in the pith. Distal to the peduncle the vascular bundles subdivide to form a eustele; large oil cells are distributed in the cortex of the peduncle, each containing a globose, yellowish-brown, transparent body. Such cells also occur in the foliicle walls.

Fig. 3 Cross-section of adaxial opening of a follicle. Arrows indicate simple trichomes. Note the short funicle (f) extending from the marginal rib. Scale bar, 50 μ m.

Fig. 4 Ovule structure. *a*, Median longitudinal section of two ovules. Note the small globose structure (*g*) attached to the micropylar end of each ovule. Scale bar, 0.2 cm. *b*, Details of the micropylar end of an ovule. ooi, Outer layer of outer integument; loi, inner layer of outer integument; ii, inner integument. Scale bar, 50 μ m.

Based on the polycarpelous floral structure of numerous conuplicate carpels and the relatively primitive wood structure composed of mainly scalariform vessels with scalariform perforation plates, the fossil is assigned to the Magnoliales. Monimiaceae and Austrobaileyaceae are the most closely comparable families, having similar concave receptacles with apocarpous carpels. However, the carpel of these families is more specialized in lacking a prominent stigmatic crest. Carpels of Monimiaceae have a single ovule, whereas those of Austrobaileyaceae have 8–14 (ref. 12). Because the present fossil has many primitive characteristics, it is difficult to assign it to a modern family.

The carpel, with a long stigmatic crest and a large number of ovules, is unknown in any living magnoliatean, but the compressed flower *Archaeanthus* Dilcher and Crane^{7,10} from the mid-Cretaceous of Kansas is comparable in this feature and also in having oil cells in the carpel walls. *Lesqueria* Crane and Dilcher and other unnamed fruits also from mid-Cretaceous of Kansas and Texas¹¹ have comparable follicle structures. The fossils differ, however, in the shape of the receptacles. All the above flowers and fruits other than the unnamed one have either elongate or ovoid receptacles on which the follicles are helically arranged, more like a living *Magnolia* flower. Note that in the early stages of magnoliatean evolution, flowers evidently existed that had two quite different forms of receptacles, both of which bore carpels possessing similarly primitive features.

Although the fossil record of the early angiosperms is limited, it demonstrates through time and space the characteristics that

have existed in the evolutionary history of angiosperms. More detailed knowledge of the Cretaceous diversification of angiosperms requires further comparative studies of both fossil and living angiosperm flowers. For the present specimen to be compared with flowers or fruits of living Magnoliales, further knowledge is needed about the ontogeny and anatomy of carpels and receptacles, ovule structure, carpel arrangement and wood anatomy of living members. The use of cladistic analysis may provide a more objective evaluation of such comparative data^{3,13,14}. This method may be one of the more effective ways of answering such basic questions as what the angiosperms are, when and from what kind of ancestors they may have originated, and how they have diversified.

I thank Professors M. Nishida and W. D. Tidwell for advice and encouragement and for reading the manuscript.

Abolition of specific immune response defect by immunization with dendritic cells

Claire J. P. Boog, W. Martin Kast,
H. Th. Marc Timmers, Jolande Boes,
Leo P. de Waal & Cornelis J. M. Melief

Central Laboratory of the Netherlands Red Cross Blood Transfusion Service, incorporating the Laboratory of Experimental and Clinical Immunology of the University of Amsterdam, PO Box 9406, 1006 AK, Amsterdam, The Netherlands

Murine cytotoxic T (T_c)-cell responses to various antigens are controlled by immune response (*I*r) genes mapping in the major histocompatibility complex (*H*-2). The genes responsible are those encoding the class I and class II *H*-2 antigens^{1–4}. The *H*-2 *I*-A^b mutant mouse strain bm12 differs from its strain of origin, C57BL/6 (*H*-2^b), only in three amino acids in the *I*-A^b class II *H*-2 molecule^{5–7}. As a consequence, female bm12 mice are T_c -cell nonresponders to the male antigen H-Y and do not reject H-Y disparate skin grafts⁸. We now report that bm12 mice generate strong H-Y-specific T_c cells following priming *in vivo* and restimulation *in vitro* with male bm12 dendritic cells (DC). Female bm12 mice primed with male DC also reject male skin grafts. Furthermore, we demonstrate that only responder cell populations containing a mixture of L3T4⁺ (T-helper (T_h) phenotype) and Lyt 2⁺ (T_c phenotype) T lymphocytes generate H-Y-specific T_c cells. These data imply an essential role for T_h cells, activated by DC as antigen-presenting cells (APC), in changing H-Y-nonresponder bm12 mice into H-Y responders. Priming and restimulation with DC allows the triggering of a T-cell repertoire not demonstrable by the usual modes of immunization. This principle might be used to overcome other specific immune response defects.

Effective T_c -cell responses to at least some antigens are elicited only in mice possessing 'responder' alleles at both class I and

class II *H-2* loci. Thus, C57BL/6 (B6) mice generate a strong *H-2D^b*-restricted *T_c*-cell response to H-Y by virtue of the presence of the *I-A^b* and *D^b* 'responder' alleles^{2,3}, illustrating effective *T_h* and *T_c* precursor activation pathways, respectively.

Previous work has demonstrated that nonresponsiveness of bm12 mice to H-Y is caused by a defect in the *T_h* repertoire³. Recently, dendritic cells were shown to be extremely effective in presenting antigen to *T_h* lymphocytes⁹⁻¹³. We therefore investigated whether it was possible to overcome the specific inability of bm12 mice to respond to H-Y by using dendritic cells as APC. To this end we used male DC to immunize female bm12 mice, and to restimulate their spleen cells *in vitro*. The ability of DC to activate H-Y-specific *T_c*-cell precursors was compared with that of bm12 normal spleen cells (NSC) and lipopolysaccharide (LPS)-stimulated bm12 lymphoblasts. Spleen cells from bm12 female mice primed by intraperitoneal (i.p.) injection of 10^7 syngeneic male NSC failed to mount an H-Y-specific *T_c* response, irrespective of the type of cell used for *in vitro* restimulation (Fig. 1); even addition of the growth factor interleukin-2 (IL-2) during the *in vitro* restimulation did not result in the generation of H-Y-specific *T_c* cells. In agreement with previous results^{3,8}, all other tested immunization procedures including intravenous (i.v.) and subcutaneous footpad immunization¹⁴ with NSC failed to yield H-Y-specific *T_c* responses (data not shown). After priming *in vivo*, followed by restimulation *in vitro*, with male bm12 LPS blasts, a very weak H-Y-specific *T_c* activity was elicited. Strikingly, however, bm12 spleen cells generated strong H-Y-specific *T_c* activity when syngeneic male DC were used both for priming and for *in vitro* restimulation. Priming with DC followed by restimulation with NSC yielded negative results. In this case, however, addition of IL-2 resulted in an H-Y-specific *T_c* response (Fig. 1).

The biological significance of these findings was evaluated further using skin grafting experiments. Unprimed B6 mice or B6 mice primed with B6 male NSC all rejected male skin grafts with mean survival times of ± 23 days (Table 1). Male skin grafts on unprimed bm12 females or bm12 females primed with syngeneic NSC showed mean survival times of >120 days. McKenzie *et al.*¹⁵ showed that female bm12 mice were unable to reject male skin grafts unless they had received prior footpad priming with male NSC; the rejection rate was significantly slower than in other primed strains. As stated previously, we were unable to demonstrate H-Y-specific *T_c* responses in bm12 mice after footpad immunization³. In contrast, priming of bm12 females with male DC led to a dramatic decrease of male graft survival (mean time for graft rejection = 22 days; Table 1). In fact, bm12 mice primed with DC rejected their skin grafts as quickly as B6 mice primed with NSC (group 2; Table 1). The difference in survival time between the DC-primed bm12 mice and the control group was highly significant ($P < 0.001$; compare groups 6 and 4 in Table 1). All graft rejections were H-Y-specific, because all animals were also grafted with female grafts, which all survived indefinitely (>120 days). The important *in vivo* role of DC in graft rejection has also been demonstrated in allograft models^{17,18}.

Further experiments indicated the necessity for H-Y antigen to be present on the DC used for priming, because immunization

Fig. 1 H-Y-specific *T_c* response of bm12 *I-A* mutant mice following various modes of immunization.

Methods. Dendritic cells were isolated as described by Steinman *et al.*¹⁶. Briefly, spleen cells were spun on a discontinuous bovine serum albumin (BSA) gradient of 10, 28 and 35% BSA ($\rho = 1.099, 1.080$ and 1.031) for 30 min at $10,000g$. The interphase (α band) 10–28% was removed and cultured for 90 min in glass Petri dishes. Non-adherent (Nad) cells were discarded and the medium was replaced. After a further 18 h in culture, Nad cells were separated by Fc receptor (FcR) rosetting. FcR-positive and FcR-negative (dendritic) cells were then separated over a discontinuous 10–31% BSA gradient. Fractionation of NSC yields a recovery of 9–12% α -band cells, 0.3–0.5% 18-h Nad cells and finally 0.1–0.2% FcR-negative dendritic cells. H-Y-specific *T_c* cells were generated as described previously³ with minor modifications. Briefly, spleen cells (10^7) from *in vivo*-primed bm12 female mice were stimulated with irradiated (2,500 rad) male spleen cells (10^7), LPS blasts (10^6) or DC (10^5) in 2 ml medium for 5 days at $37^\circ C$ in humidified air with 5% CO_2 . Effector cells were tested on ^{51}Cr -labelled male and female bm12 LPS target cells (15×10^3) at various effector/target (E/T) ratios. The results shown are those obtained at E/T = 16 (mean of five experiments, s.e.m. indicated by bars). The % lysis on female bm12 LPS target cells was always $<6\%$. The supernatant of concanavalin A-stimulated rat spleen cells (final concentration 25% in culture medium) was used as a source of IL-2.

with female DC admixed with male NSC was ineffective (data not shown). From the results shown in Fig. 1 we conclude that only after priming of bm12 female mice *in vivo* with bm12 male DC are H-Y-specific *T_h* cells activated; the latter are needed for the generation of sufficient numbers of *T_c* memory cells. This is reflected in the finding that only after priming *in vivo* with male DC can the requirement for *T_h* cells *in vitro* be circumvented by the addition of IL-2 (Fig. 1).

Table 1 Effect of priming of bm12 female mice with male dendritic cells (DC) on the rejection of H-Y disparate skin grafts

Group	Mice	Immunization	Grafted with	No.	MST \pm s.d. (days)	P
1	B6 ♀	PBS	B6 ♂	14	22.5 \pm 6	
2	B6 ♀	B6 ♂ NSC	B6 ♂	8	22.6 \pm 4.0	0.10 (NS)
3	B6 ♀	B6 ♂ LPS	B6 ♂	11	11.2 \pm 4.7	0.05
4	bm12 ♀	PBS	bm12 ♂	15	>120	
5	bm12 ♀	bm12 ♂ NSC	bm12 ♂	15	>120	>0.20 (NS)
6	bm12 ♀	bm12 ♂ DC	bm12 ♂	8	21.9 \pm 2.1	<0.001

Mice were either unprimed or primed i.p. 3 weeks before skin grafting. All animals were also grafted with syngeneic female grafts which all survived indefinitely (>120 days). MST, mean survival time. P values were measured using the χ^2 test in comparison with phosphate-buffered saline (PBS) controls (groups 1 and 4 respectively for B6 and bm12). NS, not significant. LPS, LPS-stimulated lymphoblasts.

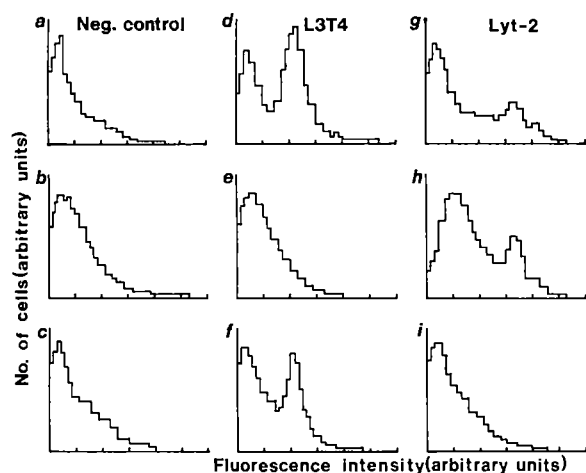

Fig. 2 Flow microfluorimetric analysis of untreated (*a, d, g*) and anti-L3T4+complement (*b, e, h*) or anti-Lyt2+complement (*c, f, i*)-treated bm12 responder cell populations (see Fig. 3 for functional analysis). Linear fluorescence histograms are expressed in arbitrary units.

Methods. After passage through nylon wool, bm12 female responder spleen cells ($2 \times 10^7 \text{ ml}^{-1}$) were incubated in Iscove's medium, 0.5% BSA, with anti-Lyt 2.2 (a mouse monoclonal antibody, 1:1,000 dilution of ascites fluid; NEN) or anti-L3T4 (a rat monoclonal antibody, 1:40 dilution of hybridoma culture supernatant SN 172-4; given by Dr H. R. MacDonald). After incubation for 45 min at room temperature, low-tox-M rabbit complement (Cedarlane) was added to a 1:10 final dilution. After incubation for 45 min at 37 °C, the cells were washed and the complement treatment was repeated. Treated cells were passed over lympholyte-M (Cedarlane; density = 1.0875). Viability was >90% and cell recovery after passage through nylon wool and treatment with L3T4 or Lyt 2+C' was $2 \pm 0.7\%$ and $3.1 \pm 0.9\%$, respectively (mean \pm s.d. of five experiments). For flow microfluorimetric analysis, aliquots of 5×10^5 untreated L3T4-negative or Lyt 2-negative responder cells in 100 μl were incubated at 4 °C with the following rat monoclonal antibodies: *a-c*, no antibody; *d-f*, anti-L3T4 (1:50 dilution of hybridoma culture supernatant H129-19 (ref. 30), provided by M. Pierres); *g-i*, anti-Lyt 2 (1:4 dilution of hybridoma culture supernatant 53-6.7 (ref. 31), provided by J. Ledbetter). After 30 min the cells were washed and $25 \mu\text{g ml}^{-1}$ of fluorescein isothiocyanate-conjugated rabbit anti-rat immunoglobulin (KR 116F, CLB) was added for an additional 30 min at 4 °C. Control samples were stained with second-step reagent only. Cells were washed three times and all samples were passed through a flow cytometer (FACS IV; Becton and Dickinson).

In further experiments we attempted to analyse whether, during *in vitro* restimulation, bm12 mutant DC stimulate L3T4⁺ T_h cells, or whether they are possibly more efficient in stimulating Lyt 2⁺ precursors of H-Y-specific helper-independent cytolytic cells. Therefore, we treated responder spleen cells with either anti-L3T4 or anti-Lyt 2 monoclonal antibody plus complement (C'), then cultured these cells with male DC as stimulator cells. Flow cytometric analysis of aliquots of the different responder cell populations (Fig. 2) showed that almost no L3T4⁺ (Fig. 2*e*) or Lyt 2⁺ cells (Fig. 2*i*) were detected after treatment with antibody and complement compared with untreated cells (Fig. 2*a, d, g*). Treatment with anti-Lyt 2 plus C', as expected, resulted in complete abrogation of the H-Y-specific T_c response (Fig. 3, population 4). In addition, after removal of L3T4⁺ T_h cells from the responder cell population, no significant H-Y-specific T_c response was generated (Fig. 3, population 3). These effects were due to the specific elimination of either L3T4⁺ or Lyt 2⁺ cells, as the response could be completely restored by mixing these two treated populations (Fig. 3, population 5). We conclude that bm12 male DC are more efficient in stimulating T_h cells than T_c precursors.

It is unknown why DC can so efficiently activate T_h cells, resulting in the abolition of the H-Y-specific immune response defect in bm12 mice. A direct relationship has been postulated

Fig. 3 Effect of responder cell treatment with anti-L3T4 or anti-Lyt 2 monoclonal antibodies plus complement on the generation of an H-Y-specific T_c response of bm12 I-A mutant mice after priming and restimulation with bm12 male DC. Treatment of responder cells: population (1) untreated; (2) medium plus complement alone; (3) anti-L3T4 plus complement; (4) anti-Lyt 2 plus complement; (5) a mixture of responder cells treated with anti-L3T4+complement (1×10^6) or anti-Lyt 2+complement (1×10^6), respectively [populations (3) and (4)].

Methods. The different cell populations were isolated as described in Fig. 2 legend. Responder cells (2×10^6) from bm12 female mice primed *in vivo* with bm12 male DC (10^5) were cultured with irradiated (2,500 rad) bm12 male DC stimulator cells (10^5) in 200 μl of culture medium in 96-well round-bottomed microtitre plates (Flow Laboratories). After 5 days of incubation in humidified air with 5% CO₂ at 37 °C, various dilutions of the effector cells were tested on ⁵¹Cr-labelled male and female bm12 LPS target cells (5×10^3). The % lysis on female target cells was always <5%.

between APC function and the number of APC surface Ia molecules¹⁹⁻²²; our results could be in agreement with this notion as bm12 splenocytes are reported to express only 25-50% as much class II antigen as B6 splenocytes^{4,23,24}, and because DC express a large number of class II molecules^{25,26}. On the other hand, DC can be expected to overcome nonresponsiveness also in cases where no quantitative differences in class II molecules between responder (R) and nonresponder (NR) strains exist (C.J.P.B., unpublished results). In general, these effects of DC can be ascribed to (1) high expression of class II molecules and (2) qualitative properties of DC as cells specialized for the APC function. Usually, T cells from F₁ hybrids between R and NR strains respond only to R-type and not to NR-type APC^{27,28}; this finding neither proves nor negates defective antigen presentation by APC as the cause of nonresponsiveness (discussed by Nagy *et al.*²⁹). We previously reported, however, that (B6 \times bm12)F₁ T cells generated an H-Y-specific T_c response to either R-type B6 or NR-type bm12 male APC³, indicating that in the bm12 mouse nonresponsiveness is not caused by defective antigen presentation but by a T-cell repertoire defect³. Despite the fact that the T_c response defect of bm12 mice can be overcome by immunization with DC, the repertoire defect for stimulation by NSC is still present: after priming with DC and restimulation with NSC no H-Y-specific T_c response occurs, unless IL-2 is added to the culture medium. Indeed, the H-Y-specific T-cell repertoire elicited by the DC immunizations is a clearly different one, because it requires not only priming but also restimulation with male DC. This DC-unique repertoire probably reflects the presence of T_h cells capable of responding to high-density I-A molecules and H-Y antigen on the surface of DC. The arousal of this dormant repertoire by immunization with DC has clear implications for states of autoimmunity, immunodeficiency and transplantation immunity.

We thank H. R. MacDonald for providing the cytotoxic anti-L3T4 monoclonal antibody, M. Pierres and J. Ledbetter for their gifts of anti-L3T4 and anti-Lyt 2 monoclonal antibodies (provided through Drs A. Van Agthoven and J. Hilgers, respectively), Eric Philippus and Evert de Vries for operating the FACS IV, and Gertrude Damhuis for preparing the manuscript. This work

was partly supported by the Foundation for Medical Research (FUNGO) which is subsidized by the Netherlands Organization for the Advancement of Pure Research (ZWO).

Phosphatidylinositol is the membrane-anchoring domain of the Thy-1 glycoprotein

Martin G. Low & Paul W. Kincade

Oklahoma Medical Research Foundation, 825 NE 13th Street, Oklahoma City, Oklahoma 73104, USA

Glycoproteins exposed on cell surfaces are commonly anchored in the membrane via hydrophobic peptide domains which penetrate the lipid bilayer¹. However, it has recently been appreciated that there are exceptions to this generalization and certain cell-surface proteins appear to be anchored via a specific association with phosphatidylinositol²⁻⁷. Thy-1 glycoprotein may also be attached to cell membranes by a non-protein hydrophobic domain located at the C-terminus and although the chemical nature of this moiety has not been determined, it was postulated that it might be a lipid⁸. On the other hand, amino-acid sequences predicted from nucleotide sequence analyses suggest that a C-terminal hydrophobic peptide segment not found in the purified, detergent-solubilized Thy-1 glycoprotein may be responsible for attachment⁹⁻¹¹. We report here that a highly purified phospholipase C specific for phosphatidylinositol selectively released Thy-1 from viable normal or malignant T lymphocytes. This result supports the proposed lipid nature of the Thy-1 anchoring domain⁸ and further suggests that this lipid is, or is closely related to, phosphatidylinositol.

EL-4 murine thymoma cells were incubated with phosphatidylinositol-specific phospholipase C (PI-PLC) purified from *Staphylococcus aureus* culture supernatants¹². The cells were washed in media, stained with fluorescently labelled anti-Thy-1 antibodies and analysed by flow cytometry. Treatment with PI-PLC produced substantial decreases in cell-surface Thy-1, as indicated by a downward shift in relative cell fluorescence (Fig. 1a). The reduction in Thy-1 density after PI-PLC treatment

Fig. 1 Cells were incubated with PI-PLC or pronase and analysed for surface antigen as described in Table 1 legend. For clarity, the location of the unstained controls is not shown, but data from this and other experiments normalized with respect to unstained controls are shown in Table 1. *a*, Thy-1 antigen on EL4 cells; *b*, 14.8 antigen on 70Z/3 cells.

Fig. 2 A hypothetical model for Thy-1 membrane attachment. As no hydrophobic peptide domains are present in mature Thy-1 and it is released from the membrane by PI-PLC, the acyl chains of phosphatidylinositol are proposed to be entirely responsible for membrane anchoring as a result of hydrophobic interactions within the lipid bilayer. The Thy-1 polypeptide is covalently attached at the C-terminal amino-acid residue (cysteine) to the inositol ring of phosphatidylinositol via a structure (X) which at present is unidentified but appears to contain ethanolamine, glucosamine and galactosamine⁸. Similarly, the nature of the X-phosphatidylinositol linkage is unknown but probably involves one of the five free hydroxyl groups on the inositol ring.

typically amounted to a 50% reduction in logarithmically expressed fluorescence intensity and, in some experiments, a proportion of the cells was completely denuded of antigen. The effect of PI-PLC on Thy-1 was not restricted to tumour cells, as a reduction in surface Thy-1 fluorescent labelling was also observed when normal thymocytes prepared from mouse thymus were treated with PI-PLC (Table 1). By contrast, treatment of the cells with pronase (at a concentration 100 times greater than that of PI-PLC) produced a relatively small decrease in the amount of cell fluorescence (Fig. 1a, Table 1). This result indicates that Thy-1 is relatively insensitive to proteolysis, as suggested by a previous study¹³, and that loss of Thy-1 from the cell surface as a result of PI-PLC treatment is probably not due to a minor proteolytic contaminant of the highly purified PI-PLC. This view was further strengthened by the observation that other lymphocyte surface proteins such as the 14.8 antigen (on 70Z/3 cells) and the transferrin receptor (on EL4 cells) were not removed by PI-PLC even though these proteins are highly sensitive to pronase (Fig. 1b, Table 1).

The transferrin receptor has previously been shown to contain covalently bound fatty acid but it is not known whether this is involved in membrane anchoring¹⁴. It should be emphasized that PI-PLC purified by the procedure used here has previously been shown to have no detectable proteolytic activity against a

Table 1 Effect of phosphatidylinositol-specific phospholipase C on lymphocyte surface antigens

Antigen	Cells	Treatment	Fluorescence intensity (% of control)
Thy-1	EL4	PI-PLC (<i>S. aureus</i>)	51.4 ± 12.6 (7)
		Pronase	83.1 ± 10.7 (4)
		PLC (<i>B. cereus</i>)	97.6 (1)
		PLC (<i>C. perfringens</i>)	98.5 (1)
Thy-1	Mouse thymocytes	PI-PLC (<i>S. aureus</i>)	58.0 (2)
		Pronase	70.0 (1)
		PLC (<i>B. cereus</i>)	94.9 (1)
		PLC (<i>C. perfringens</i>)	96.4 (1)
Transferrin receptor	EL4	PI-PLC (<i>S. aureus</i>)	101.7 ± 31.5 (3)
		Pronase	0.8 (2)
14.8	7OZ/3	PI-PLC (<i>S. aureus</i>)	103.6 ± 4.2 (3)
		Pronase	26.9 (2)

Cells (10^6 ml^{-1}) were incubated for 60 min at 37°C in RPMI 1640/HEPES medium containing bovine serum albumin (2 mg ml^{-1}), DNase I ($200 \mu\text{g ml}^{-1}$; Calbiochem) and 2-mercaptoethanol ($5 \times 10^{-5} \text{ M}$) plus the following additions as indicated above: phosphatidylinositol-specific phospholipase C (PI-PLC), $20 \mu\text{g ml}^{-1}$ (purified from *S. aureus* culture supernatants)¹²; pronase, 2 mg ml^{-1} (*Streptomyces griseus* protease; Sigma); phospholipase C (PLC), 1 U ml^{-1} (*Bacillus cereus* grade I; Boehringer Mannheim); PLC, 5 U ml^{-1} (*Clostridium perfringens* type XII; Sigma). With the last two treatments, similar results were obtained at 10- and 100-fold lower concentrations (data not shown). The cells were centrifuged, resuspended in fresh medium and stained with fluorescently labelled antibodies. Thy-1 was demonstrated using monoclonal rat anti-mouse Thy-1.2 (clone 30-H12; Becton-Dickinson)²⁹ and monoclonal mouse anti-mouse Thy-1.2 (clone HO-13-14, from the American Type Culture Collection)³⁰; these were used as purified, directly labelled or biotin-labelled antibodies. The murine receptor for transferrin was revealed using monoclonal rat antibodies (clone R17 217) given by Dr Ian Trowbridge³¹. Monoclonal rat anti-14.8 antibody detects a macromolecule which is preferentially expressed on B-lymphocyte lineage cells³². Purified, fluorescein-labelled mouse anti-rat immunoglobulin antibodies were used as a second-step reagent as described previously³². A total of 10,000 cells per sample was evaluated with a Coulter EPICS V flow cytometer. Fluorescence was recorded as arbitrary units (channel numbers) on a logarithmic scale and median intensities determined (channel number above which 50% of cells were included). Data from individual experiments were normalized with respect to the fluorescence of unstained control samples and values are expressed as percentages ($\pm \text{s.d.}$) of the fluorescence intensities in the stained control samples. Values in parentheses are the total number of determinations in five independent experiments.

variety of substrates, to be extremely selective in the membrane components that it releases, and to hydrolyse only phosphatidylinositol and its derivatives^{3,7,15-18}. The specificity of the releasing effect of PI-PLC was further demonstrated by the observation that treatment of EL4 cells or thymocytes prepared from normal mouse thymus with two other phospholipases C which are unable to hydrolyse phosphatidylinositol^{19,20} did not have any effect on the amount of Thy-1 on the cell surface (Table 1). Thus, release of Thy-1 by PI-PLC is unlikely to be due to a physical effect resulting from perturbation of membrane structure (for example, microvesiculation) since degradation of cell-surface phospholipids using nonspecific phospholipases C would produce at least as much 1,2-diacylglycerol as the PI-PLC. The observation that the transferrin receptor and 14.8 antigen are not released (Fig. 1b, Table 1) would also argue against such a mechanism. In this regard, note that all other proteins released by PI-PLC have clearly been shown to be soluble, hydrophilic and of low relative molecular mass^{2-5,16}.

It has been suggested that the cell-surface proteins alkaline phosphatase, 5'-nucleotidase, acetylcholinesterase and the variant surface glycoprotein (VSG) of *Trypanosoma brucei*, are anchored to membranes by covalent attachment to phosphatidylinositol^{2,4-7,21}. The hydrophobic membrane-anchoring domains of the latter two proteins, which are located at the

C-terminus, have several unusual structural features. They contain ethanolamine, glucosamine and phosphatidylinositol (or inositol) but no hydrophobic amino acids^{6,7,21,22}, which suggests that the hydrophobic character and membrane attachment function in these proteins are due entirely to the acyl chains of the phosphatidylinositol. Some of these structural features of the C-terminal domain have also been observed in the Thy-1 antigen⁸. The data presented above clearly demonstrate that a substantial proportion of the Thy-1 expressed on the surface of thymocytes is selectively released by treatment with PI-PLC from *S. aureus*, and support the suggestion of Williams and co-workers⁸ that a covalently attached lipid, probably phosphatidylinositol (Fig. 2), is responsible for membrane attachment.

The role of lipid in the anchoring of Thy-1 to the membrane was recently challenged by the observation that the primary messenger RNA translation product of the *thy-1* gene, deduced from complementary DNA and genomic sequences⁹⁻¹¹ contains an extra sequence of 31 amino acids at the C-terminus which is not found in the mature protein⁸. Multiple genes, tissue/species differences, post-transcriptional mRNA processing, or post-translational protein processing do not appear to be responsible for this discrepancy^{10,11}. As this extra C-terminal sequence is extremely hydrophobic, Silver and co-workers suggested that it, instead of a lipid, is responsible for membrane attachment⁹⁻¹¹. However, the data presented here directly challenge this view as most of the surface Thy-1 on lymphocytes was released by a PI-PLC that does not cleave peptide bonds¹⁵⁻¹⁷.

Although Silver and co-workers found no evidence for post-translational proteolytic processing¹⁰, we propose that the discrepancy between the cDNA and amino-acid sequences arises as a result of the removal of the 31-amino-acid hydrophobic sequence from the C-terminus before further modification by addition of the phosphatidylinositol-containing structure. It is important to note that this same sequence of events has already been proposed for the biosynthesis and post-translational modification of the VSG of *T. brucei*^{7,23,24}. It is possible that multiple forms of Thy-1 exist and our studies, which are concerned with only those molecules exposed at the murine lymphocyte surface, do not preclude such a possibility. However, the suggestion that artefactual losses of the hydrophobic C-terminal peptide, during purification and sequence analysis, underlie the discrepancy⁹⁻¹¹ seems unlikely.

These findings beg the question of the function of this unique form of membrane attachment for particular cell-surface proteins. In the case of the VSG of trypanosomes, a specific endogenous phospholipase C has been found⁶ and it is believed that this may be important for loss of surface antigen during differentiation^{23,24}. Thy-1 is a cell-surface glycoprotein which has been well characterized with respect to distribution in animals and man, appearance in ontogeny, and amino-acid sequence²⁵. Although the function of Thy-1 is unknown, it is thought to be a member of an immunoglobulin-like family of cell-surface molecules which are involved in recognition processes^{25,26}. It is not clear whether circumstances exist in which Thy-1 is released from neuronal and lymphoid cell surfaces. However, as phosphoinositide-specific phospholipases C, which are widely distributed in mammalian tissues, are believed to be activated during cell stimulation²⁷, this possibility should be considered.

Since submission of this paper, we learned of more detailed analyses of the hydrophobic C-terminal domain of Thy-1 (ref. 28) which reveal the presence of inositol, phosphate, glycerol and fatty acid. This result strongly supports the argument presented here that phosphatidylinositol is the membrane-anchoring domain of Thy-1.

We thank M. A. J. Ferguson, A. H. Futerman, W. R. Sherman, I. Silman and T. L. Rosenberry for helpful discussions, Dr I. Trowbridge for antibodies, and M. Robinson for technical assistance. This work was supported by NIH grants HL-28985 and AI-20069.

Thrombospondin binds falciparum malaria parasitized erythrocytes and may mediate cytoadherence

Plasmodium falciparum infected erythrocytes containing mature trophozoites and schizonts sequester along venular endothelium¹ and are not in the peripheral circulation of patients with malaria. Knobs appear on infected erythrocytes and are the points of attachment to endothelium². Sequestration may protect the parasite from splenic destruction³ and may play a role in the pathogenesis of cerebral malaria⁴. Correlates of sequestration have been developed *in vitro* using cultured human endothelium⁵ and an amelanotic melanoma cell line⁶. Knobless strains (K-) of *P. falciparum* fail to sequester *in vivo* and to bind to cells *in vitro*. We now present evidence that the receptor for cytoadherence is the glycoprotein, thrombospondin. *Aotus* monkey or human erythrocytes containing knobby (K+) but not *Aotus* erythrocytes containing knobless strains of *P. falciparum* bind to immobilized thrombospondin. Neither binds to the adhesive proteins laminin, fibronectin, factor VIII/von Willebrand factor or vitronectin. Both soluble thrombospondin and anti-thrombospondin antibodies inhibit binding of parasitized *Aotus* erythrocytes to immobilized thrombospondin and to melanoma cells which secrete thrombospondin.

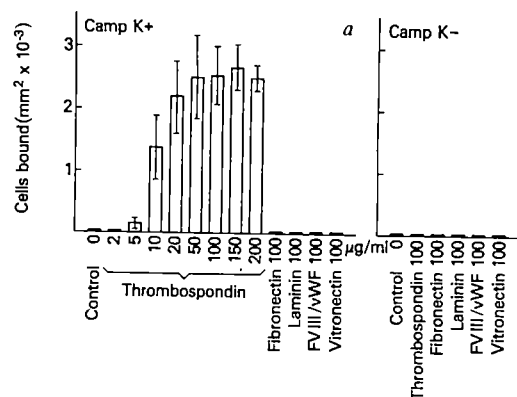

Fig. 1 Binding of *P. falciparum* parasitized erythrocytes to adhesive proteins adsorbed on plastic. *a*, K+ strain; *b*, K- strain.

Methods. Knobby (K+) and knobless (K-) variants of Malayan Camp strain *P. falciparum*²² were maintained in Columbian night monkeys (*Aotus trivirgatus griseimembra*)²⁶. Blood with 20-40% parasitaemia was cryopreserved as rings²⁷. The rings were thawed, cultured for 20-30 h to mature trophozoites and schizonts^{25,28}, washed twice in RPMI 1640, and resuspended to a 1.5-2.0% haematocrit in RPMI 1640. Viable platelets and leukocytes do not survive the cryopreservation and were not seen in the cultures. Calcium-replete human platelet TSP (isolated as described in ref. 20), human plasma fibronectin (Collaborative Research, Inc.), mouse laminin¹⁰, human factor VIII/von Willebrand factor (FVIII/vWF)²⁹, and human plasma vitronectin¹¹ in phosphate-buffered saline pH 7.4, containing 1 mM CaCl₂, were adsorbed onto bacteriological plastic dishes (Falcon 1007) by incubation in a humidified atmosphere for 3 h at 25 °C or overnight at 4 °C. These conditions result in efficient adsorption of the proteins based on immunoreactivity of adsorbed TSP¹⁴ and promotion of cell adhesion by adsorbed fibronectin, laminin and vitronectin^{9,11,30}. Control disks were incubated with phosphate-buffered saline alone. A circular area 3 mm in diameter coated with protein could be reproducibly obtained using a 10-µl drop of protein solution. After incubation, the protein solution was aspirated and the plate was immediately immersed into 50 mM Tris-buffered saline pH 7.8, containing 1% bovine serum albumin, 5 mM CaCl₂ and 0.1 mM phenylmethylsulphonyl fluoride to minimize nonspecific binding. After 30-60 min at 25 °C, the plate was rinsed in RPMI 1640 and overlaid with a suspension of parasitized erythrocytes. The plates were incubated at 37 °C for 60 min with gentle agitation every 15 min, washed by dipping in RPMI 1640, fixed for 2 h in phosphate-buffered saline, pH 7.4, containing 1% glutaraldehyde, and stained with 1% Giemsa. Results are presented as the mean \pm 1 s.d. ($n=4$).

Several adhesive glycoproteins are associated with endothelial cells or are present in blood, including thrombospondin (thrombin-sensitive protein⁷, glycoprotein G⁸, TSP), fibronectin⁹, laminin¹⁰, vitronectin¹¹ and factor VIII/von Willebrand factor¹². Adherence of Malayan Camp strain K+ *P. falciparum* parasitized *Aotus* erythrocytes to plastic surfaces coated with each of these glycoproteins or with serum albumin was tested (Fig. 1). Parasitized erythrocytes adhered avidly to surfaces coated with TSP but not to surfaces coated with laminin, fibronectin, factor VIII/von Willebrand factor, vitronectin or serum albumin. Adherence to TSP was detectable using 5 µg ml⁻¹ TSP for coating and was maximal at 50 µg ml⁻¹ TSP. Of the cells bound to TSP, 85-95% contained parasites (Fig. 2), whereas the parasitaemia of the erythrocytes used in this assay was only 10%. Uninfected erythrocytes cultured under the same conditions used for the parasitized cells did not bind to any of the proteins tested. Binding to TSP is specific for erythrocytes containing mature trophozoites or schizonts. Ring forms, the immature parasites within erythrocytes, do not sequester *in vivo* and did not bind to TSP.

A Camp K- strain of *P. falciparum*³ was also examined for adherence to proteins adsorbed on plastic (Fig. 1*b*). K- parasitized *Aotus* erythrocytes did not bind to TSP or the other adsorbed proteins. The correlation between knobby phenotype

Table 1 Binding of erythrocytes parasitized with different strains of *Plasmodium falciparum* to thrombospondin and to C32 melanoma cells

Parasite strain	No. of parasitized erythrocytes bound:	
	Per mm ² of thrombospondin-coated plate*	Per 100 melanoma cells†
<i>Aotus</i> erythrocytes		
Camp K+	7,100 ± 240	1,960 ± 90
Camp K-	25 ± 32	5 ± 2
St Lucia K+	4,100 ± 600	1,040 ± 50
St Lucia K-	30 ± 27	7 ± 3
Human erythrocytes		
Brazil ItG2F6	600 ± 350	170 ± 90
Vietnam/Cambodia (V1)	530 ± 350	290 ± 80
Thailand (T2)	220 ± 160	70 ± 30
Kenya (K3)	210 ± 140	35 ± 10
Liberia (L)	100 ± 90	115 ± 90
Nigeria (N1)	40 ± 60	50 ± 50

Parasites of the Malayan Camp²² and St Lucia²³ strains were maintained in *Aotus* monkeys and cultured synchronously to 6–20% total parasitaemia by the methods described in Fig. 1 legend. K+ and K- strains were maintained in non-splenectomized and splenectomized monkeys, respectively³. Parasites of the Brazil (ItG2F6 (ref. 24), a clone by limit dilution of It), Vietnam/Cambodia (V1), Thailand (T2), Kenya (K3), Liberia (L) and Nigeria (N1) strains all have knobs¹³ and were cultured in O⁺ human erythrocytes with O⁺ serum²⁵, cryopreserved and thawed²⁷, and cultured asynchronously in fresh erythrocytes for 10–20 days to 2–14% total parasitaemia (0.3–6% mature trophozoites and schizonts). TSP and melanoma binding assays were done four times during this period. Binding assays were performed as in ref. 6 and in Fig. 1. Binding of unparasitized erythrocytes to TSP-coated plates was 86 ± 40 cells mm⁻².

* Mean ± s.d., n = 4.

† Mean ± s.d., n = 5.

and TSP binding was further examined using another strain of *P. falciparum* (Table 1). As was found with the Camp strain, *Aotus* erythrocytes infected with the St Lucia K+ strain, but not the St Lucia K- strain, bound avidly to TSP. Only K+ strain parasitized erythrocytes bind to melanoma⁶ and endothelial cells⁵. Thus both sequestration and binding to TSP require knobs.

Although knobs are necessary for sequestration⁶, they are not sufficient¹³. Knob-positive strains of *P. falciparum* after continuous culture *in vitro* have decreased binding to melanoma or endothelial cells¹³. The strains It, V1, T2, K3, L and N1 all have knobs¹³. We measured the binding to TSP of these K+ strains cultured in human erythrocytes (Table 1). All bound at reduced levels to both TSP and melanoma cells. The two strains that bound best to melanoma cells, ItG2F6 and V1, bound best to TSP. Thus, the knobby phenotype appears to be necessary but not sufficient for TSP adherence. These results also demonstrate that parasitized human erythrocytes bind to TSP.

Further evidence that TSP is a receptor on the melanoma surface for binding of *Aotus* parasitized erythrocytes is twofold. First, preincubation of parasitized erythrocytes with soluble thrombospondin inhibited adherence both to immobilized TSP and melanoma cells (Table 2). Using 200 µg ml⁻¹ TSP, binding to TSP was inhibited 91%, and binding to melanoma cells was inhibited 81%. In a control experiment, preincubation of parasitized erythrocytes with 200 µg ml⁻¹ laminin did not inhibit binding. Second, preincubation of the melanoma cells or TSP-coated plates with rabbit anti-TSP immunoglobulin but not non-immune rabbit immunoglobulin inhibited binding (Table 2). As was the case with TSP inhibition, the antibody was more effective in inhibiting binding to TSP than binding to melanoma cells. Similar results were obtained using the monoclonal mouse antibody to TSP, A2.5 (ref. 14) (Table 2), whereas two other mouse monoclonal anti-TSP antibodies, A6.1 and C6.7 (ref. 14), did not inhibit attachment (data not shown).

Table 2 Inhibition of parasitized erythrocyte binding to immobilized thrombospondin and melanoma cells by soluble thrombospondin and anti-thrombospondin antibodies

Inhibitor	Final concentration (µg ml ⁻¹)	% Of control binding to:	
		Immobilized thrombospondin	Melanom. cells
Soluble thrombospondin	20	ND	89
	50	65	ND
	100	18	ND
	200	9	19
Rabbit anti-thrombospondin antibody	4	105	110
	12	88	ND
	40	20	63
	125	3	32
Non-immune rabbit IgG	125	120	90
Mouse monoclonal anti-thrombospondin A2.5	50	15	51

Rabbit anti-TSP antibodies and mouse monoclonal anti-TSP antibody A2.5¹⁴ were purified on Affigel-protein A (Bio-Rad). To determine the effect of TSP on binding, Camp K+ strain parasitized *Aotus* erythrocytes with 10% parasitaemia were incubated at 2% haematocrit in RPMI 1640 containing different concentrations of purified TSP at 25 °C for 30 min and then placed over TSP-coated plates (100 µg ml⁻¹) or formalin-fixed C32 melanoma cells. The TSP binding assay was continued as in Fig. 1. The melanoma cytoadherence assay was performed as in ref. 6. To determine the effect of rabbit anti-TSP antibody and mouse monoclonal anti-TSP antibody 2.5 on binding, TSP-coated plates (100 µg ml⁻¹) and melanoma cells were incubated in different concentrations of antibodies in RPMI 1640 at 25 °C for 30 min. To this solution was added a volume of parasitized erythrocytes at 10% parasitaemia and 50% haematocrit such that the final haematocrit was 2%. The TSP binding and melanoma cytoadherence assays were continued as above. ND, not determined.

A solid-phase radioimmunoassay for TSP using rabbit anti-TSP immunoglobulin coated on 96-well microtitre plates in 0.1 M sodium carbonate, pH 9.6, and ¹²⁵I-TSP¹⁵ (10 µCi µg⁻¹, 50 ng ml⁻¹) was used to detect TSP synthesis by C32 melanoma cells. To remove immunoreactive bovine TSP, melanoma cells which had been grown in RPMI 1640 containing 10% fetal bovine serum were preincubated for 16 h in medium containing 10% heat-inactivated horse serum, which does not contain immunoreactive TSP. For determination of TSP secretion, fresh medium containing 10% horse serum was incubated with the cells for 24 h, centrifuged for 10 min at 1,000g and assayed by radioimmunoassay. Dilutions of TSP in 10% horse serum were used as standards. The melanoma cells secreted 13 µg TSP per 10⁶ cells per 24 h. Human umbilical cord endothelial cells also synthesize and secrete TSP¹⁶. Thus, both target cells for cytoadherence *in vitro*, the melanoma cells and human endothelial cells, produce TSP. Immunofluorescence analysis of bovine aortic endothelial cells¹⁷ suggested that TSP is localized both intracellularly and as a component of fibrillar extracellular matrix.

A trypsin-sensitive strain-specific plasmodial protein of relative molecular mass 260,000–285,000 (ref. 18) on the surface of K+ but not K- parasitized erythrocytes¹⁹ has been implicated as a ligand for cytoadherence. However, the parasite could also expose a host ligand for TSP binding. TSP agglutinates trypsinized glutaraldehyde-fixed erythrocytes²⁰ and sulphated glycoconjugates on the fixed erythrocyte probably mediate agglutination¹⁵. The sulphated polysaccharides heparin and fucoidan bind to TSP and inhibit fixed erythrocyte agglutination¹⁵. We have shown that TSP binds parasitized erythrocytes and that heparin and fucoidan do not inhibit this binding (D.D.R., unpublished results). Therefore, a different site on TSP is probably recognized by the parasite.

Although parasitized erythrocytes bind directly to TSP adsorbed onto plastic, TSP itself may not be the only molecule

Fig. 2 Binding of *P. falciparum* parasitized erythrocytes to human platelet thrombospondin. A $100 \mu\text{g ml}^{-1}$ solution of TSP was adsorbed onto plastic dishes, and binding of Malayan Camp K+ parasitized *Aotus* erythrocytes was determined as described in Fig. 1. The dishes were fixed in 100% methanol and stained with Giemsa. The granular material bound to a 3-mm circular area coated with TSP (*a*, $\times 17$) consists of stained parasitized erythrocytes viewed at high magnification in *b* ($\times 300$).

required for cytoadherence. Since TSP is a soluble protein, receptors for TSP are probably present on the cell membrane or extracellular matrix of melanoma cells. Thus other melanoma surface molecules may be necessary in conjunction with TSP for cytoadherence. Requirement for a TSP receptor is also suggested by the finding that some cell lines which secrete TSP in culture do not bind parasites (J.A.S., manuscript in preparation).

We have established that K+ strains of *P. falciparum* in *Aotus* erythrocytes attach specifically to immobilized TSP but not to other cell adhesion molecules. K+ strains of *P. falciparum* in fresh human erythrocytes also attach to TSP. TSP is produced by both melanoma and endothelial cells¹⁶ and may be on the surface of these cells. This evidence, combined with the blocking of cytoadherence to melanoma cells by TSP and by antibodies to TSP, is consistent with the hypothesis that TSP is a melanoma and endothelial cell receptor for *P. falciparum* cytoadherence. Binding of *P. falciparum* strains to TSP correlates well with binding to melanoma cells *in vitro*. Binding to melanoma cells correlates well with binding to endothelial cells^{6,13} and with sequestration *in vivo*^{6,21}. Sequestration occurs at specific vascular sites, including cardiac venules¹. If TSP is the receptor for cytoadherence *in vivo*, endothelium in these vessels may selectively express TSP on their luminal surfaces.

We thank Drs Harvey Gralnick, Lance Liotta and Erkki Ruoslahti for providing purified factor VIII/von Willebrand factor, laminin and vitronectin, respectively.

Collagen fibres form the stable architecture of connective tissues and their breakdown is a key irreversible step in many pathological conditions^{1,2}. The destruction of collagen is usually initiated by proteinases, the best known of which is the metalloproteinase collagenase (EC 3.4.24)³. Collagenase and related metalloproteinases are regulated at the level of their synthesis and secretion, through the action of specific stimuli such as hormones and cytokines, and also at the level of their extracellular activity through the action of a specific inhibitor, TIMP (tissue inhibitor of metalloproteinases)⁴⁻⁶, which irreversibly forms inactive complexes with metalloproteinases⁷. Although the mechanisms governing the production of TIMP are unknown, immunologically identical forms of this glycoprotein have been detected in a wide variety of human body fluids and cell and tissue culture media^{5,8}. We therefore suggested⁵ that under physiological conditions this ubiquitous inhibitor predominates over active metalloproteinases and that tissue destruction may arise when any perturbation of this controlling excess arises. However, further progress towards testing this theory has been hindered by a lack of knowledge about the structure of TIMP and insufficient material for studying it in model systems. Here we describe the structure of TIMP predicted from its complementary DNA, its synthesis in *Escherichia coli* and transfected animal cells, and the finding that it is identical to a protein recently reported to have erythroid-potentiating activity (EPA)⁹.

TIMP was sequenced after purification from human amniotic fluid¹⁰ and from the culture media of human fetal lung fibroblasts (American Type Culture Collection CCL153). Figure 1*a* compares these N-terminal sequences with that published for a collagenase inhibitor¹¹, with properties similar to TIMP⁸, that is produced by human skin fibroblasts. Human amniotic fluid and human fetal lung TIMP are identical for all 28 N-terminal amino acids identified. Except for a leucine (instead of lysine at position 22) the human skin fibroblast inhibitor is also identical for 23 N-terminal residues¹¹ (Fig. 1*b*). Based on this information, we constructed a single 69-base oligonucleotide probe capable of encoding the 23 N-terminal amino acids of TIMP¹² (Fig. 1*c*). The codons used were those reported to appear most frequently in human genes, except in three positions where to

Fig. 1 N-terminal amino-acid sequences of human fetal lung fibroblast and human amniotic fluid TIMP (a) and of human skin fibroblast collagenase inhibitor (b). c, The 69-base oligonucleotide probe; d, the complementary 18-mer. The numbers above the probe sequence refer to the nucleotide sequence of the cDNA (Fig. 2b). The letters above the probe sequence represent those nucleotides that are different in the cDNA.

Methods. Human fetal diploid lung cells (ATCC CCL153) purchased at passage 13 (Flow Laboratories) were maintained in Dulbecco's modified Eagle's medium (DMEM; Gibco) supplemented with 4 mM glutamine, 15% heat-inactivated fetal calf serum (FCS) and 100 IU ml^{-1} penicillin and 100 $\mu\text{g ml}^{-1}$ streptomycin. Cells were expanded into two 490- cm^2 plastic roller bottles, allowed to reach confluence in growth medium, washed with serum-free DMEM and then maintained in serum-free media for up to 6 days. Culture supernatant TIMP was measured by inhibition of rabbit skin collagenase using the collagen fibril assay¹⁰. One unit of TIMP inhibits 2 units of collagenase (2 μg of collagen degraded per min) by 50%. TIMP levels varied from <0.2 U to 5 U per 10^5 cells per 48 h, and low-producing cells were stimulated by the addition of 5 ng ml^{-1} 4 β -phorbol-12 β -myristate-13 α -acetate (PMA) to the serum-free culture medium²⁴. Culture supernatants and cells were collected after 6 days, the former being concentrated 40-fold with an Amicon concentrator using a Diaflo hollow-fibre cartridge with a M_r -10,000 cut-off. TIMP was purified from the concentrated supernatants¹⁰ and reduced and carboxymethylated by standard procedures. TIMP from human amniotic fluid was similarly purified¹⁰, reduced and carboxymethylated. The NH_2 -terminal sequence was determined by automated Edman degradation on an Applied Biosystems gas-phase sequencer. The 69-mer oligonucleotide probe was synthesized on an Applied Biosystems model 380A synthesizer by monomer addition of activated phosphoamidites to a solid support. The deprotected probe was purified by HPLC. The 18-mer was synthesized by automated solid-phase phosphotriester chemistry²⁵ and also purified by HPLC.

Fig. 2 a, Restriction map of human TIMP cDNA compiled from one almost full-length cDNA and the 5' end (broken line) of one additional overlapping cDNA. The open boxes represent pBR322 sequences. The arrows denote directions of dideoxy sequencing. P, *Pst*I; N, *Nco*I; T, *Tth*III-1; B, *Bst*XI; M, *Mst*II; A, *Ava*I; V, *Pvu*I; H, *Hae*II; I, *Hin*fl. b, Nucleotide sequence of human TIMP and the predicted amino-acid sequence. The numbers beneath the sequence refer to the mRNA sequence. The nucleotides at positions 27 and 706 were not identified. The numbers above the sequence refer to the amino-acid sequence; negative numbers refer to the signal sequence. Potential glycosylation sites are underlined.

Methods. mRNA was isolated from washed CCL153 cells by the guanidinium isothiocyanate/hot phenol method²⁶, followed by oligo(dT)-cellulose (Collaborative Research) column chromatography²⁷. Standard procedures were used to synthesize cDNA²⁸ and a library of 20,000 colonies was established by C-tailing the cDNA into G-tailed²⁹, *Pst*I-cut pBR322 and transforming the annealed DNA into *E. coli* DH1 (ref. 30). The colonies were transferred to nitrocellulose filters and screened with the 69-mer labelled at the 5' end to a specific activity of 2×10^7 c.p.m. μg^{-1} . Hybridization was in 0.9 M NaCl, 0.09 M Tris-HCl pH 7.4, 0.006 M EDTA, 0.5% Nonidet P-40, 2 \times Denhardt's solution, 0.2% SDS for 16 h at 42 $^{\circ}\text{C}$ with a probe concentration of 25 ng ml^{-1} . High-stringency washing of the filters (0.5 \times SSC, 0.1% SDS for 15 min at 50 $^{\circ}\text{C}$) was followed by autoradiography for 20 h with an intensifying screen. Ten putatively positive clones were identified, six of which gave positive signals after a second screening. Plasmid DNA was isolated and used as a template for T-tracking using the 18-mer as a primer^{31,32}. Five of the six clones were found to have related sequences over a region of at least 70 nucleotides and restriction mapping was used to confirm the relatedness of these clones. The complete nucleotide sequence of clone 2 (the longest clone), with some additional 5' sequence from clone 3, was determined by the dideoxy method³² using either the 18-mer to prime sequencing directly on plasmid DNA³¹ or after subcloning restriction fragments into M13 tg130 or tg131 (Amersham) and transformation into *E. coli* JM101 (ref. 33).

have included such codons would have incorporated the rarely observed dinucleotide, CpG (refs 13, 14). In addition, an 18-mer complementary to nucleotides 25–42 of the long probe was also constructed (Fig. 1d).

The 69-mer was used to identify positive colonies from a cDNA library of 20,000 clones derived from human fetal lung fibroblast messenger RNA. Restriction mapping (Fig. 2a) and partial DNA sequencing using the 18-mer as a primer revealed that five positive colonies harboured plasmids with related cDNA inserts. These were shown to be putative TIMP cDNAs by end-labelling the 18-mer and using it to prime dideoxy sequencing of the longest clone. The complete nucleotide sequence compiled from this and one other clone is shown in Fig. 2b. Examination of the sequence reveals that there is an open reading frame coding for a protein of 207 amino acids.

Evidence that the sequence encodes TIMP comes from the observation that nucleotides 133–216 encode the 28 N-terminal amino acids of human amniotic fluid and fetal lung fibroblast TIMP, including the lysine at position 22 identified by amino-acid sequencing (Fig. 1a). As the methionine encoded by nucleotides 64–66 is the only one in any reading frame upstream from the N-terminal amino acids, it is assumed that amino acids –23 to –1 (many of which are hydrophobic) represent a signal sequence that is cleaved off to liberate mature protein¹⁵. Unprocessed TIMP with the signal sequence is therefore predicted to have a relative molecular mass (M_r) of 23,144; this approximates to the size of TIMP core protein (M_r , 22,000) obtained after immunoprecipitation of the *in vitro* translation products of human fetal lung fibroblast mRNA¹⁰. Furthermore, the predicted M_r of unglycosylated mature TIMP is 20,685, which is consistent

Fig. 3 Northern blot of CCL153 and HL60 mRNA probed with TIMP cDNA. *a*, CCL153 cell mRNA; *b*, mRNA from HL60 cells grown without stimulation; *c*, mRNA from HL60 cells stimulated with phorbol esters and lipopolysaccharide (LPS).

Methods. The CCL153 cells were grown as described in Fig. 1 legend. The HL60 cells were grown in a similar medium and stimulated to differentiate¹⁹ by incubation with 3×10^{-6} M PMA for 2 h, then washed and incubated for 10 h in the presence of $1 \mu\text{g ml}^{-1}$ LPS (Sigma; L-2880). mRNA was isolated as described in Fig. 2 legend and $5 \mu\text{g}$ was electrophoresed in a 1.25% agarose gel containing 8% formaldehyde, transferred to nitrocellulose and hybridized in $5 \times \text{SSC}$, $5 \times$ Denhardt's solution, 50% formamide, $300 \mu\text{g ml}^{-1}$ denatured salmon sperm DNA, 0.1% SDS, 50 mM Na_2HPO_4 pH 6.5 for 16 h at 42°C with 30 ng ml^{-1} of purified *Pst*I fragments of the cDNA shown in Fig. 2, labelled by nick-translation to a specific activity of 2×10^8 c.p.m. μg^{-1} . The filters were washed in $0.1 \times \text{SSC}$, 0.1% SDS at 60°C for 30 min and autoradiographed for 8 h. RNA sizes were estimated by running 18S and 28S RNA and ^{32}P -labelled denatured λ DNA digested with *Cla*I in parallel.

with the finding that TIMP immunoprecipitated from culture supernatants of CCL53 cells grown in the presence of tunicamycin had a M_r of 20,000 (20K)¹⁶. As tunicamycin inhibits the assembly of dolichol-linked oligosaccharides for the formation of asparagine-linked sugar chains on glycoproteins¹⁷, it is likely that most, if not all, the oligosaccharide chains on TIMP are *N*-linked. Two potential *N*-glycosylation sites are indicated in Fig. 2b.

The poly(A) tract preceded by the polyadenylation signal AATAAA at the 3' end of the cDNA indicates that the 3' end of the mRNA is represented¹⁸. Furthermore, a single band of ~800 nucleotides was observed after Northern blotting of mRNA from human fetal lung fibroblasts with TIMP cDNA, indicating that the cDNA was very close to full length (Fig. 3a). A similar-sized single band was also observed after probing mRNA from HL60 cells which had been stimulated with phorbol esters to achieve monocyte differentiation¹⁹ (Fig. 3b, c).

To confirm that the cDNA described above encodes TIMP, part of the cDNA without the signal sequence but with an additional N-terminal methionine was inserted into the *E. coli* expression vector pMG196 (E.M.W., G. O. Humphreys and G. T. Yarranton, in preparation) to produce pMG454 (Fig. 4a). In this plasmid the *trp* promoter is used to drive transcription of the inserted TIMP cDNA. pMG454 exists stably in *E. coli* at low copy number in the absence of selection but on induction increases in copy number to 100–200 per chromosome. As shown in Fig. 4c, after induction of *E. coli* cells harbouring pMG454, we observed a protein of M_r 20,000, the expected size for unglycosylated TIMP. Note that β -lactamase (which is also encoded by pMG454) was also specifically induced. By Western blotting it was shown that the 20 K protein reacts with polyclonal antibodies directed against TIMP purified from human amniotic fluid²⁰ (Fig. 4d, lane 2). As with several other recombinant proteins expressed in *E. coli*²¹, TIMP was found to be mostly in an insoluble form in inclusion bodies (data not shown).

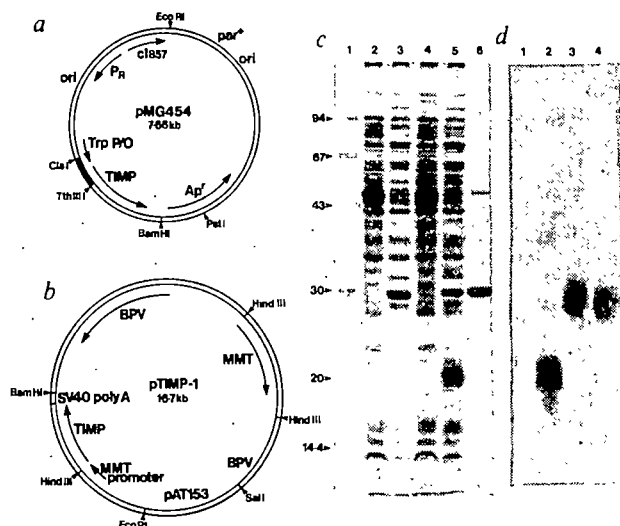

Fig. 4 *a*, *b*, Restriction maps (not to scale) of the *E. coli* expression vector pMG454 and the mammalian cell expression vector pTIMP-1, respectively. In pMG454 the solid box represents the 61-base pair (bp) linker. *c*, A 12% SDS-polyacrylamide gel showing Coomassie blue-stained proteins made in *E. coli* E103S transformed with pMG454. Lane 1, marker proteins; lane 2, non-induced control cells harbouring the expression vector with no TIMP cDNA insert; lane 3, induced control cells; lane 4, non-induced E103S cells harbouring pMG454; lane 5, as lane 4 but induced; lane 6, purified *E. coli* β -lactamase. *d*, Autoradiograph obtained after Western blotting with the TIMP antibody. Lanes 1 and 2, as lanes 4 and 5 in *c*; lane 3, purified human amniotic fluid TIMP; lane 4, culture supernatant proteins from a C127 cell line transfected with pTIMP-1.

Methods. For insertion into both expression vectors, the *Hinf*I site adjacent to the TIMP stop codon (Fig. 2) was converted with a linker into a *Bam*HI site. For expression in *E. coli* the 5' end of the cDNA was reconstructed using a 61-bp linker to provide an upstream *Cla*I site followed by an ATG start codon preceding the cysteine codon at the N-terminus of mature TIMP. The resulting TIMP-coding fragment was ligated into the dual-origin vector pMG196 and transformed into *E. coli* E103S (a proteinase-deficient K-12 derivative). Cultures of E103S containing the resulting plasmid (pMG454) were grown at 30°C in L-broth to an A_{600} of 0.4, then shifted to 42°C by shaking at 65°C . On reaching 42°C they were transferred to a 37°C water bath and grown for a further 5 h, after which appropriately sized aliquots were taken and analysed by SDS-gel electrophoresis³⁴ and Western blotting³⁵. For expression in mammalian cells the *Nco*I site adjacent to the ATG start codon was converted with a linker into a *Hind*III site. The entire TIMP coding sequence was then inserted downstream from the *MMT* promoter in the BPV-based vector shown above (P.E.S., M. M. Bendig and C. C. Hentschel, manuscript in preparation). After transfection into C127 cells³⁶ by calcium phosphate co-precipitation³⁷, CdCl_2 (20 μM)- and ZnCl_2 (20 μM)-resistant foci were selected. Their ability to secrete TIMP was measured after 16 h of growth in serum-free media by a competitive RIA based on immobilized specific antibodies to TIMP²⁰, Western blotting³⁵, and a collagen fibril assay as described for CCL153 cells (Fig. 1).

The cDNA was also inserted into a vector designed for expression in mammalian cells (Fig. 4b). The coding sequence of pre-TIMP was inserted between the murine metallothionein (*MMT*) promoter and the simian virus 40 early transcript polyadenylation signal in a bovine papillomavirus (BPV)-based vector²². This plasmid (pTIMP-1) also has a functional *MMT* gene which confers heavy-metal resistance on mammary fibroblast tumour cells (C127 cells) harbouring it. Calcium phosphate co-precipitation was used to introduce pTIMP-1 DNA into these cells and nine resistant foci were selected for further study. Radioimmunoassays (RIAs) for TIMP were performed on culture supernatants after 16 h in serum-free medium. The polyclonal antibodies directed against purified human amniotic fluid TIMP, which are known not to cross-react with bovine or murine

TIMP²⁰, detected a 200-fold increase of TIMP in some of the pTIMP-1-transfected cell lines compared with control cells transfected with the plasmid without inserted cDNA. Highest yields of up to 1.5–2.0 $\mu\text{g ml}^{-1}$ TIMP were obtained. In addition, Western blotting indicated that the TIMP secreted by the transfected C127 cells had a M_r identical to authentic TIMP purified from human amniotic fluid, suggesting that in these cells the recombinant TIMP is correctly processed and glycosylated (Fig. 4d, lane 4). To determine whether the immunoreactive TIMP made in the C127 cells was biologically active, the culture supernatants were tested for their ability to inhibit rabbit skin collagenase using the collagen fibril assay¹⁰ (see Fig. 1 legend). No activity was detected in the supernatants of those cells shown by RIA to be making undetectable amounts of TIMP. However, 2–5 U ml^{-1} TIMP was detected in the supernatants of those cells shown in the RIA to be making in excess of 500 ng ml^{-1} TIMP, indicating that pTIMP-1 directs the synthesis of active TIMP in C127 cells. Further refinement of pTIMP-1-harboring cell lines should permit a greater yield of active TIMP.

The N-terminal sequences indicate that TIMP and the human skin fibroblast inhibitor are identical. Their overall amino-acid composition is also very similar, which is in keeping with the finding that these commonly occurring inhibitors, together with others of M_r 28,000 (28K) identified in many human tissues^{5,8}, are immunologically and functionally identical. The cDNA predicts the presence of 12 cysteine residues, which is in contrast to the larger number (24 half-cystines) reported for the skin fibroblast inhibitor¹¹ but which is consistent with the cysteine content reported for a bovine metalloproteinase inhibitor²³. Recently, Gasson *et al.*⁹ reported the N-terminal sequence of a 28K protein reported to have erythroid-potentiating activity (EPA) that was purified from medium conditioned by human T-cell lymphotropic virus type II (HTLV-II)-infected Mo T-lymphoblast cells. This N-terminal sequence and the predicted amino-acid sequence of the corresponding cDNA are identical to those reported here for TIMP. Although these data suggest that the enzyme inhibitor (TIMP) may have lymphokine activity on specific cells of the erythroid lineage, it will first be necessary to determine whether TIMP prepared by our methods has erythroid-potentiating activity. The TIMP-synthesizing *E. coli* and mammalian cell lines should also permit the purification of sufficient TIMP for a thorough study of the cellular mechanisms that normally prevent uncontrolled resorption. Furthermore, the primary structure of TIMP described here will provide a starting point for designing new compounds for controlling disease processes in which accelerated breakdown of extracellular matrices is a prominent feature.

We thank the following at Celltech: Joanna Hales and Kathy Lambert for growing the CCL153 cells, John Kenton for growing the HL60 cells, Chris Bose and Thakor Patel for synthesizing the oligonucleotide probes, Mark Bodmer and Sarah Whitham for help with analysis of TIMP cDNAs, Gillian Alcock for typing the manuscript and our many colleagues for fruitful discussions. We thank Robin Ward and Penny McLaughlan for help with radioimmunoassays and Chris McAlpine for help with the purifications. Work at SRL is supported by funds from the MRC.

L-myc, a new myc-related gene amplified and expressed in human small cell lung cancer

Marion M. Nau, Burke J. Brooks, James Battey, Edward Sausville, Adi F. Gazdar, Ilan R. Kirsch, O. Wesley McBride*, Virginia Bertness, Gregory F. Hollis & John D. Minna

NCI-Navy Medical Oncology Branch and *Laboratory of Biochemistry, National Cancer Institute, National Institutes of Health & Naval Hospital, Bethesda, Maryland 20814, USA

Altered structure and regulation of the c-myc proto-oncogene have been associated with a variety of human tumours and derivative cell lines, including Burkitt's lymphoma^{1,2}, promyelocytic leukaemia^{3,4} and small cell lung cancer (SCLC)⁵. The N-myc gene, first detected by its homology to the second exon of the c-myc gene, is amplified and/or expressed in tumours or cell lines derived from neuroblastoma^{6–8}, retinoblastoma⁹ and SCLC¹⁰. Here we describe a third myc-related gene (L-myc) cloned from SCLC DNA with homology to a small region of both the c-myc and N-myc genes. Human genomic DNA shows an EcoRI restriction fragment length polymorphism (RFLP) of L-myc defined by two alleles (10.0- and 6.6-kilobase (kb) EcoRI fragments), neither associated disproportionately with SCLC. Mouse and hamster DNAs exhibit a 12-kb EcoRI L-myc homologue, which indicates conservation of the gene in mammals. Gene mapping studies assign L-myc to human chromosome region 1p32, a location distinct from that of either c-myc^{1,11} or N-myc¹² but associated with cytogenetic abnormalities in certain human tumours¹³. This L-myc sequence is amplified 10–20-fold in four SCLC cell line DNAs and in one SCLC tumour specimen taken directly from a patient. Either the 10.0- or 6.6-kb allele can be amplified and in heterozygotes only one of the two alleles was amplified in any SCLC genome. SCLC cell lines with amplified L-myc sequences express L-myc-derived transcripts not seen in SCLC with amplified c-myc or N-myc genes. In addition, some SCLCs without amplification also express L-myc-related transcripts. Together, these findings suggest an enlarging role for myc-related genes in human lung cancer and provide evidence for the concept of a myc family of proto-oncogenes.

While examining genomic DNA from human SCLC cell lines for evidence of c-myc and N-myc amplification, we occasionally observed a number of additional EcoRI fragments, including 10.0- and 6.6-kb fragments that hybridized to either a second-exon c-myc probe¹⁴ or to the homologous region of the N-myc gene (pNb-1)⁶ (see Fig. 1a). We speculated that these EcoRI

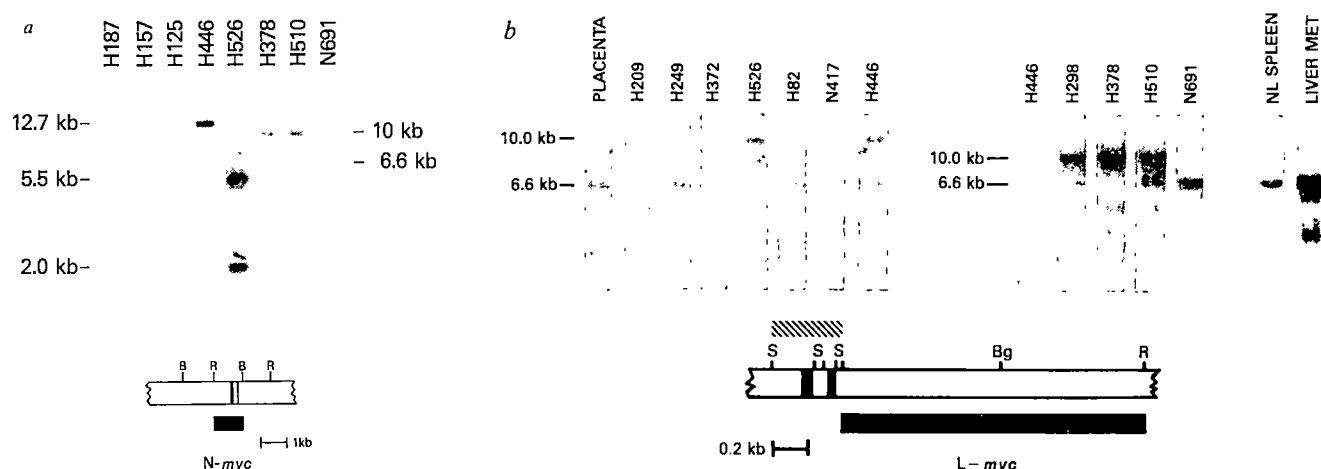

Fig. 1 *a*, Detection of novel *myc*-related sequences in *Eco*RI digests of SCLC cell line DNAs with a human *N-myc* probe. *b*, Hybridization comparison of *Eco*RI digests of SCLC cell line and patient tissue sample DNAs with a human *L-myc* probe. In *a*, the *N-myc* probe is a 1.0-kb *Eco*RI–*Bam*HI fragment (horizontal solid bar) obtained from clone pNb-1 isolated from a human neuroblastoma cell line⁶. The 12.7-kb position represents the *Eco*RI germline *c-myc* gene fragment¹ (which is seen with the *N-myc* probe when it is amplified as in H446); the 2.0-kb position, the *Eco*RI germline *N-myc* fragment⁶ seen in all DNAs in *a* and amplified in H526 (ref. 10); the 5.5-kb position, a putative *N-myc*-related gene sequence found and amplified in H526 (ref. 10); the 10.0-kb (H378 and H510) and 6.6-kb (N691) positions, the *Eco*RI *myc*-related gene fragments representing *L-myc*. In *b*, the *L-myc* probe used is the 1.8-kb *Sma*I–*Eco*RI fragment²⁷ obtained from clone pLmyc 10. The characteristic 10.0-kb *Eco*RI DNA fragment of *L-myc* was isolated by preparative gel electrophoresis²⁷ of an *Eco*RI digest of SCLC cell line H378 genomic DNA and cloned into CH4A phage²⁸. Five clones were identified using either the Nb-1 *N-myc* probe⁶ or the second-exon 1.6-kb *Sst*I–*Sst*I *c-myc* probe¹. One of these clones was subcloned into pJB327 (a derivative of pBR327)²⁹ and was termed pLmyc 10. The 10.0-kb and 6.6-kb positions represent the *Eco*RI genomic *L-myc* fragments. The degree of *L-myc* amplification was determined by cutting-out and liquid scintillation counting of the ³²P-labelled 10.0-kb and 6.6-kb *L-myc* bands from the Southern hybridization blot shown in *b*. The c.p.m. of each amplified band was divided by the average c.p.m. of a single non-amplified allele to obtain an approximate amplification value, after background c.p.m. was subtracted from both. Heavy vertical solid lines indicate regions of homology between *c-myc*, *N-myc*⁶ and *L-myc* DNA sequences; the hatched block indicates the region sequenced (see Fig. 3 legend). Restriction endonuclease sites are indicated as follows: B, *Bam*HI; R, *Eco*RI; S, *Sma*I; and Bg, *Bgl*II.

Methods. The NCI-series of cell lines that were established, characterized and grown in our laboratory^{22,23} include SCLC lines H82, H187, H209, H249, H298, H372, H378, N417, H446, H510, H526 and N691, and non-SCLC lines H125 and H157. Cell line DNA was prepared as described elsewhere²⁴, while tumour and normal tissue samples collected directly from the patient at autopsy were first pulverized in liquid nitrogen in a blender before DNA extraction. Then 12 µg of each DNA was digested with *Eco*RI, electrophoresed on a 0.8% agarose gel, denatured and transferred to nitrocellulose essentially as described by Southern²⁵. Hybridization was performed using 10% dextran sulphate²⁶ with the ³²P-labelled probe indicated on the schematic map and washed at 52 °C in 0.1 × SSC, 0.1% SDS as described previously¹.

Fig. 2 Hybridization comparison of poly(A)⁺ and total SCLC cell line RNAs with a human *L-myc* probe. The 5.1-kb and 2.0-kb positions indicate 28S and 18S human ribosomal RNAs respectively.

Methods. Total cellular RNA was prepared by guanidine thiocyanate–caesium chloride gradient centrifugation³⁰. Several RNAs were further enriched by oligo(dT)–cellulose chromatography³¹. Then 10 µg of total RNA or 2 µg of poly(A)⁺ RNA was denatured and electrophoresed on a 1% agarose–formaldehyde gel³², modified by using 0.22 M formaldehyde in the gel and electrophoresing at 160 V for 4 h. Transfer, hybridization and washing were as described elsewhere³³.

myc-hybridizing fragments might represent other *myc*-related genes which were also amplified in some SCLC cell line DNAs.

To test this hypothesis, the novel 10.0-kb *Eco*RI DNA genomic fragment from human SCLC cell line NCI-H378 was cloned from *Eco*RI size-fractionated DNA and designated pLmyc 10 (see Fig. 1*b* legend). The partial pLmyc 10 restriction endonuclease map obtained (Fig. 1*b*) is markedly different from those of *c-myc*¹⁴, *N-myc*⁶ and three other *myc*-related clones described earlier¹⁵. Using restriction endonucleases, various subfragments of pLmyc 10 were subcloned, including the 1.8-kb *Sma*I–*Eco*RI fragment (see map, Fig. 1*b*). We have termed this new *myc*-related sequence *L-myc* because it was first isolated from a human lung cancer cell line.

Using the *Sma*I–*Eco*RI fragment as a probe, we then screened *Eco*RI digests of 40 SCLC cell line DNAs for *L-myc* sequences using Southern blot analysis (see Fig. 1*b* for examples). In addition to the expected 10.0-kb *Eco*RI DNA fragment, we also observed hybridization to the 6.6-kb *Eco*RI fragment in several DNAs (including human placental DNA). DNAs were identified that contained either both *Eco*RI fragments (10.0 and 6.6 kb) or only one fragment (10.0 or 6.6 kb). Since a number of other restriction endonuclease digests (*Bgl*II, *Sst*I, *Bam*HI and *Hind*III) show no pattern differences between DNAs (data not shown), these two *Eco*RI fragments identified represent an *Eco*RI restriction site polymorphism outside the *Sma*I–*Eco*RI *L-myc* probe, rather than a tumour-specific somatic rearrangement. The presence of the two alleles, however, raises the question of an association between lung cancer and the alleles, as was recently suggested for the *ras* oncogene family¹⁶. We scored 40 SCLC DNAs, 30 cell line DNAs of other tumour types including adenocarcinoma of the lung, neuroblastoma and retinoblastoma, as well as the lymphocyte DNAs of 13 normal individuals. There were no major differences in the *L-myc* allele frequencies among the three groups. Overall, 24 DNAs were 10.0-kb homozygotes, 22 DNAs were 6.6-kb homozygotes and 37 were heterozygotes. Pooling data from all tumour cell lines

Diagram illustrating the structure of the *c-myc* gene and its transcripts. The top part shows the *c-myc* gene structure with exons represented by boxes and introns by lines. The 5' and 3' ends are indicated. A scale bar indicates 500 bp. Below the gene structure, four transcripts are shown, each with its corresponding nucleotide sequence and amino acid sequence (aa.).

strands. A hatched block in Fig. 1b indicates the region of pLmyc 10 sequenced. The nucleotide sequence was determined by the dideoxynucleotide chain termination method³⁴ essentially as described elsewhere³⁵. Certain sequences were confirmed by chemical sequencing as described by Maxam and Gilbert³⁶.

Experiments also revealed several SCLC cell line DNAs, including H378, amplified for either the 10.0-kb or 6.6-kb *Eco*RI DNA fragment (NCI lines H298, 10-fold; H378, 20-fold; H510, 15-fold; and N691, 10-fold), when compared with other SCLC cell line DNAs (Fig. 1b). In addition, a SCLC tumour sample obtained directly from a patient at autopsy showed an approximate 15-fold amplification of L-*myc* DNA when compared with the patient's normal tissue DNA (Fig. 1b). Some DNAs amplified for either the 10.0-kb and 6.6-kb *Eco*RI L-*myc* fragments show other uncharacterized hybridizing species (H378

L-*myc* gene expression was examined in a group of SCCL cell lines, including those that showed L-*myc* amplification. All cell lines amplified for the L-*myc* sequences show a 2.2-kb transcript in poly(A)⁺-selected RNA using the 1.8-kb *Sma*I-*Eco*RI fragment as a probe (Fig. 2). It is of interest that H378 poly(A)⁺

Detection of the human *L-myc* gene (10.0-kb and 6.6-kb *EcoRI* fragments) correlated with the presence or absence of various human chromosomes in 65 mouse-human and Chinese hamster-human primary hybrids and subclones. Discordancy represents either the presence of a specific human chromosome in the absence of human *L-myc* or the presence of this sequence despite the absence of the chromosome in that hybrid. The *L-myc* locus can be assigned to that chromosome with the lowest discordancy. When two numbers are given, they refer to discordancy with short-arm and long-arm markers, respectively. The human-mouse hybrids consist of 15 primary clones and 17 subclones of 5 additional hybrids¹⁷⁻¹⁹ and 12 contained the human *L-myc* sequence. The hamster-human hybrids consist of 23 primary¹⁷⁻¹⁹ and 10 subclones; 12 were positive for human *L-myc*. Thirty-four of the hybrids came from crosses segregating the 10.0-kb allele, 25 came from crosses segregating the 6.6-kb allele and for the remaining 6 the RFLP pattern of the parents was not determined. The hybrid cell line DNAs also provided additional information on the subchromosomal localization of *L-myc* on human chromosome 1. One mouse-human hybrid contained the 6.6-kb *L-myc EcoRI* allele, the genes for phosphoglucomutase-1 on 1p, *N-ras* on 1p and a 6.2-kb *EcoRI* metallothionein pseudogene on 1p, but lacked the genes for peptidase C on 1q and a 2.8-kb *EcoRI* metallothionein pseudogene¹⁷. A human-hamster hybrid contained the 10.0-kb *L-myc EcoRI* allele, the 6-phosphogluconate dehydrogenase gene on 1p, phosphoglucomutase-1, enolase-1 on 1p and the metallothionein 6.2-kb sequence, but lacked the genes for peptidase C, *N-ras* and the 2.8-kb metallothionein sequence. These results strongly suggest that both the 10.0-kb and 6.6-kb *EcoRI L-myc* alleles are located on human chromosome arm 1p and are distal to the *N-ras* gene on 1p (ref. 21).

RNA shows both a 2.2-kb and a 3.8-kb RNA transcript. The origin of the novel 3.8-kb species and its relationship to the 2.2-kb RNA are unclear. One other SCLC cell line (H209) not amplified for the *L-myc* gene sequence also expresses an *L-myc* RNA transcript of 2.2 kb (see Fig. 2). Two representative SCLC lines that are amplified and express increased amounts of either *c-* or *N-myc* mRNAs (H82 and H249 respectively) contain no detectable amounts of the 2.2- or 3.8-kb *L-myc* RNA transcript (see Fig. 2). Because *c-myc*-expressing SCLC cell lines do not express *N-myc* and vice versa¹⁰, it appears that only one of these three *myc*-related genes is expressed at detectable levels in total RNA from any individual SCLC cell line thus far examined.

Previous experiments comparing *c-myc* and *N-myc* sequences have demonstrated two short regions of homology between these two genes, localized to the second exon of the *c-myc* gene⁶. To understand better the structural relationship of the *L-myc* gene to the *c-myc* and *N-myc* genes, the region of homology in *L-myc* was mapped to restriction fragments located about 100 base pairs (bp) 5' to the 1.8-kb *SmaI-EcoRI L-myc* probe (see map, Fig. 1b) and the nucleotide sequence determined. Figure 3 shows a nucleotide and predicted amino-acid comparison of the

homologous regions of the *c-*, *N-* and *L-myc* genes. Like *N-myc*, *L-myc* contains the same two regions of homology to the *c-myc* gene separated by a stretch of nucleotides that bears no resemblance to the analogous region in *c-myc*. The 5' and 3' blocks of homology show about 80% nucleotide sequence homology with the analogous regions of either *c-* or *N-myc*. An open reading frame spans the 5' and 3' blocks of homology shown in Fig. 3, including the 135-nucleotide non-homologous stretch between these two regions. The predicted amino-acid sequences for the two homology regions of *L-myc* show overall 82% and 76% homology when compared with that of the *c-myc* or *N-myc* gene respectively.

The *c-myc* gene is assigned to human chromosome 8 (refs 1, 11) while *N-myc* is assigned to chromosome 2 (ref. 12), indicating dispersion of these two genes to different autosomes. We mapped the *L-myc* gene to a human chromosome region. Southern blot analyses using the 1.8-kb *SmaI-EcoRI L-myc* probe revealed a 12-kb *EcoRI L-myc* hybridizing band in both hamster and mouse DNAs, indicating the presence of an *L-myc* homologue in these two species (Fig. 4a). Analysis of rodent-human hybrids segregating human chromosomes¹⁷⁻¹⁹ revealed either retention of the 10.0-kb or 6.6-kb fragment or neither of these human *EcoRI L-myc* fragments (Fig. 4a). A panel of 65 human-rodent hybrid clones representing 43 independent hybrids with 4 different human parents were scored for the presence or absence of human *L-myc* genes and this was correlated with the retention of each human chromosome (Table 1). Both the 10.0-kb and 6.6-kb *EcoRI L-myc* alleles segregated concordantly with human chromosome 1 and discordantly with the other human chromosomes, indicating that this autosome is the most likely location for *L-myc*.

The *L-myc* gene was also mapped using the technique of chromosome *in situ* hybridization. A total of 159 separate metaphases were analysed and the results plotted on a 400-band idiogram (Fig. 4b). Grains at 1p32 comprise 7.7% of the total grains and the probability of this distribution occurring as a random event is $P < 10^{-5}$. Thus, by both somatic cell hybridization and chromosome *in situ* hybridization techniques, the *L-myc* genes have been localized to the short arm of chromosome 1, very near or within band 1p32. This is approximately the same location to which a putative oncogene, *Blym*, was mapped²⁰ earlier but distal to the proto-oncogene *N-ras*²¹. It is interesting that the human melanoma kindred gene has also been provisionally localized to 1p (ref. 13). In addition, the *L-myc* gene and its associated *EcoRI* RFLP may prove to be a useful marker in analysing cytogenetic changes in human tumours involving the 1p32 region.

Given the well-defined and limited region of homology, it will be of great interest to see whether the three *myc* gene products have similar or related functions. SCLC cell lines that contain amplified *L-myc* DNA sequences also contain at least one *L-myc*-related RNA transcript. In addition, *L-myc* has been mapped to 1p32, a chromosomal location different from that of the *c-myc*^{1,11} or *N-myc*¹² genes. The fact that *L-myc* has been found amplified in a patient's tumour tissue, but not in the normal tissue, suggests that this gene may be important in the genesis or progression of SCLC.

We thank J. Michael Bishop and Manfred Schwab for their *N-myc* clone, Bruce Johnson for his preparation of patient tissue samples, and W. Michael Kuehl for critical review of the manuscript. The opinions expressed here are the private views of the authors and are not to be construed as official or as reflecting the views of the Department of the Navy or the Department of Defense.

Sarcoma viruses carrying *ras* oncogenes induce differentiation-associated properties in a neuronal cell line

The growth-promoting and/or differentiation-blocking activities of Kirsten (Ki-MSV) or Harvey murine sarcoma virus (Ha-MSV) on various types of cells *in vitro* are well documented¹⁻⁸. Here we report an unexpected effect of these viruses on a rat pheochromocytoma cell line, PC12. PC12 cells, which multiply indefinitely in growth medium, are known to respond to nerve growth factor (NGF) by cessation of cell division and expression of several properties resembling those of differentiated sympathetic neurones^{9,10}. We have found that Ki- and Ha-MSV mimic some, if not all, of the activities of NGF in PC12 cells, and there is evidence that the viral oncogenes, *v-Ki-ras* and *v-Ha-ras*, are responsible for this phenomenon. This system may be of value for studying the mechanism of action of the *v-ras* genes as well as the regulatory mechanism of growth and differentiation in neuronal cells.

In an initial attempt to 'super-transform' PC12 cells, we infected the cells with one of five mammalian retroviruses carrying different oncogenes. To our surprise, Ki- or Ha-MSV, carrying *v-Ki-ras* or *v-Ha-ras* respectively, induced marked morphological changes of the host cells within 2-3 days of infection, that is, enlargement of the cell bodies and extension of neurite-like processes (Fig. 1c, e). These changes were similar to those induced by NGF (Fig. 1b), but in this case it was more than 4 days before we observed processes of comparable length to those induced by the *ras*-containing viruses. Moloney (Mo) MSV, carrying the *v-mos* gene, seemed to induce some morphological changes in a few days after infection (Fig. 1f), but the cells subsequently became very large and granulous, and event-

Fig. 1 Morphology of NGF-treated or MSV-infected PC12 cells. PC12 cells were usually grown at 36 °C in DMEM (Gibco) supplemented with 5% (v/v) heat-inactivated horse serum (Flow Laboratories), 5% fetal calf serum (Mitsubishi Kasei Co.), 50 U ml⁻¹ penicillin G and 50 µg ml⁻¹ streptomycin sulphate in a humidified CO₂ incubator. Virus infection was carried out in the presence of 6 µg ml⁻¹ polybrene (Aldrich). a, Control PC12 cells cultured in the above growth medium; b, PC12 cells incubated for 7 days in growth medium containing 50 ng ml⁻¹ of 2.5S NGF (Collaborative Research, Inc.); c, e, f, PC12 cells infected with Ki-, Ha- or Mo-MSV, respectively, and incubated for 4 days in growth medium; d, PC12 cells infected with the temperature-sensitive mutant of Ki-MSV and incubated for 4 days in growth medium at a non-permissive temperature, 39 °C. Scale bar, 100 µm.

ually died. Abelson murine leukaemia virus, carrying the *v-abl* gene, did not induce long processes, although the cells became spindle-shaped (not shown) and were easily detached from dishes after prolonged incubation. Simian sarcoma virus showed no apparent effect on the morphology of PC12 cells.

Under our culture conditions (see Fig. 1 legend), PC12 cells proliferated at an average doubling time of 42 h. By contrast, Ki-MSV-infected, process-extending cells stopped dividing within 3 days (Fig. 2). A similar result was obtained with Ha-MSV (not shown). The changes induced by the *v-ras*-containing MSVs do not seem to represent mere degeneration of the cells,

because the infected cells survive for many weeks, migrating actively. It was also observed that when PC12 cells were infected by Ki- or Ha-MSV and incubated for 24 h in growth medium, they could survive and extend processes in serum-free medium. The initial incubation in serum-containing medium seemed to be required for the expression of the phenotypic changes. However, cell division did not appear necessary (more rigorous experiments to explore this point are underway).

Several lines of evidence indicated that *v-ras* genes are responsible for these changes. First, the agent responsible for the changes was probably a sarcoma virus component in each virus stock, because helper MLV alone did not induce these changes, and, moreover, the number of process-extending cells induced by each of the stocks of Ki- or Ha-MSV from several different sources was roughly comparable to the number of focus-forming units measured on a rat fibroblast cell line (data not shown). It is known that only one protein is encoded by the genome of each MSV, that is, p21^{v-Ki-ras} by Ki-MSV and p21^{v-Ha-ras} by Ha-MSV¹¹. Second, transforming viruses carrying oncogenes other than *v-ras* did not induce the same type of changes (see above). Third, a temperature-sensitive (ts) mutant¹² of Ki-MSV failed to arrest the growth of PC12 cells at non-permissive temperature, although the process-inducing activity was not completely abolished (Fig. 1d). This last observation may suggest either that viral p21 proteins have more than one functional domain, or that growth-arrest requires more activity of viral p21 than does process-induction. Partial transforming activities of the ts Ki-MSV mutant at non-permissive temperature in other cell types have been reported^{4,13}.

To determine whether the changes induced by the *ras*-containing virus are involved in neuronal differentiation, we investigated whether neurone-specific properties known to be induced by NGF are also induced by the viruses in PC12 cells. First, we observed that Ki- or Ha-MSV-infected PC12 cells contained higher activities of acetylcholinesterase (as did NGF-treated cells¹⁴) than did uninfected control cells (Table 1). Second, electrophysiological examinations revealed that the mean resting potential of Ki-MSV-infected PC12 cells, as well as of NGF-treated cells, was significantly greater than that of untreated controls (Table 2). Moreover, Ki-MSV-infected, process-extending cells showed significantly higher levels of action potentials than did control cells. Judged from the two components of action potentials (that is, low and high threshold potentials), both Na⁺ and Ca²⁺ channels seemed to develop

Fig. 2 Growth curve of Ki-MSV-infected or uninfected PC12 cells. PC12 cells were infected in suspension with Ki-MSV (MOI = ~1) and plated into a 96-well dish at ~1 cell per well with growth medium. As a control, uninfected PC12 cells were plated in the same way. After 16 h, wells containing a single cell were marked and the numbers of cells in each well were scored under a phase-contrast microscope at 24–48-h intervals. ●, Uninfected cells; ○, Ki-MSV-infected, process-extending cells.

after Ki-MSV infection, although to a lesser extent than those induced by NGF¹⁵ (Table 2).

The above results indicate that at least some of the properties associated with the induction of neuronal differentiation by NGF are also induced by Ki- or Ha-MSV in PC12 cells. This is in marked contrast to the previously known biological activities of these viruses *in vitro*, which include malignant transformation of certain cells^{1–5}, blockade of Ca²⁺-dependent differentiation of primary⁶ as well as established mouse keratinocytes⁷, and growth stimulation of differentiation-competent mouse erythrogenic cells⁸. We have observed that rat

Table 1 Acetylcholinesterase activities in PC12 cells treated with NGF or infected by Ki- or Ha-MSV

	Acetylcholinesterase activity (nmol per min per mg protein)		
	Control	NGF	Ki-MSV
Expt 1			
39.6 ± 2.2	56.1 ± 3.3	55.4 ± 2.1	ND

Expt 3			
a, In growth medium:			
24.5 ± 1.0	35.5 ± 0.8	28.1 ± 0.7	ND
b, In serum-free medium:			
ND*	44.2 ± 1.5	47.0 ± 1.6	ND

PC12 cells (3×10^5 cells per 60-mm dish) were infected with Ki-MSV (multiplicity of infection (MOI) ~1) and incubated for 5 days in growth medium (expts 1, 2, 3a) or 1 day in growth medium, then 4 days in serum-free Dulbecco's modified Eagle's medium (DMEM) (expt 3b). As controls, the same number of cells were cultured in growth medium with or without 50 ng ml⁻¹ of 2.5S NGF. The cells were collected and homogenized as described elsewhere¹⁴. A colorimetric enzyme assay was performed with homogenates from triplicate cultures for each group by the method of Ellman *et al.*²⁶. Data are given as mean ± s.e. ND, not determined.

* Control PC12 cells did not survive in serum-free medium.

Table 2 Electrophysiological properties of PC12 cells treated with NGF or infected with Ki-MSV

	Control (n = 8)	NGF (n = 11)	Ki-MSV (n = 15)
Resting membrane potential (mV)			
-22.9 ± 1.0	-28.4 ± 0.33	-27.3 ± 1.6	
Time derivative of action potential (V s ⁻¹)			
Low threshold (-20 mV):			
0	2.70 ± 0.84	1.21 ± 0.37	
High threshold (0 mV):			
0.64 ± 0.43	3.89 ± 0.40	2.20 ± 0.45	

PC12 cells (1×10^5) were infected in suspension with Ki-MSV and plated in 35-mm poly-D-lysine-coated plastic dishes with growth medium. The same number of uninfected cells were plated in medium with or without 50 ng ml⁻¹ NGF. After 8 days of incubation at 36 °C, the culture fluid was replaced with a recording buffer (130 mM NaCl, 5.4 mM KCl, 1.8 mM CaCl₂, 0.8 mM MgSO₄, 5.5 mM glucose and 10 mM HEPES, pH 7.3), and electrophysiological examination using a microelectrode was performed as described elsewhere²⁷. Cells of typical sizes and morphologies were impaled and hyperpolarized to -100 mV for 1 s, then action potentials were triggered by injecting 50-ms depolarizing current pulses. Two components with threshold potentials of about -20 mV (representing activity of voltage-dependent Na⁺ channels) and about 0 mV (activity of voltage-dependent Ca²⁺ channel) were recognized in the time derivative of action potential, and are listed separately here. In control cells, a low-threshold action potential was not evolved. Results are given as mean ± s.e.

C6 glioma, a cell line whose origin was more closely related to that of PC12, was also growth stimulated by these MSVs (unpublished observation). Therefore, the growth-arresting and differentiation-inducing effects of Ki- and Ha-MSV may be highly specific to either this particular cell line or, possibly, to neuronal cells in general.

In experiments to investigate the mechanism of action of this phenomenon, we observed that anti-NGF serum of reasonably high titre failed to inhibit the process-extension and growth-arrest induced by Ki-MSV. Also, we have not detected any biologically active factors in conditioned medium collected from Ki- or Ha-MSV-infected PC12 cultures. We therefore believe, although this has not been proved, that some intracellular reactions induced by viral p21, rather than endogenously secreted differentiation factors, may trigger the phenotypic changes described above.

Very recently, two groups of investigators have discovered phenomena related to our observation. First, D. Bar-Sagi and J. Feramisco found that the transforming Ha-ras protein—but not its normal counterpart—introduced into PC12 cells via microinjection induces process-extension and arrest of DNA synthesis (personal communication), providing further evidence that the activated p21 itself is indeed responsible for this phenomenon. Second, Alemà *et al.* found that Rous sarcoma virus, which carries the *v-src* gene, induces changes almost identical to those described here in PC12 cells¹⁶. However, the kinetics of process-induction by *v-ras* and by *v-src* seem to differ from each other; *v-ras* induces processes with a shorter lag time and at a higher rate than either NGF or *v-src*. Although the significance of this difference and the relationship of these two analogous phenomena are unclear, one possibility is that *v-ras* and *v-src* share a common pathway of action in this system. Previously, we have found that two clones of flat revertants isolated from a Ki-MSV-transformed fibroblast cell line were resistant to 'retransformation' by *v-src*-containing viruses as well as by *v-ras*-containing viruses¹⁷, suggesting some functional relationship between the two oncogenes in transformation of fibroblasts also.

The mechanism of action of NGF remains controversial^{18,19}. Hypotheses have been proposed to take account of second messengers such as cyclic AMP and Ca²⁺ (ref. 20), as well as of other signal-transducing mechanisms^{21–23} and direct translocation of the ligand-receptor complex into the cell nucleus^{18,19}. Examination of such early physiological changes in PC12 cells infected by either *v-ras*- or *v-src*-containing viruses should provide useful information on the mechanisms of action of the viral oncogenes as well as of NGF itself. To examine the role of cyclic AMP in this system is of special interest, in view of the recent discovery that the *ras*-related genes in yeast seem to serve as GTP-dependent regulatory components of adenylate cyclase^{24,25}.

We thank Drs H. Yoshikura, Y. Yuasa and H. Sugiyama for providing viruses, Dr H. Temin for valuable discussions, and Dr R. Bassin for critical reading of the manuscript. This study was partly supported by grants from the Ministry of Education, Science, and Culture of Japan, and from Tokushima Research Institute of Otsuka Pharmaceutical Co. Ltd. D.-g.L. is on leave from Shanghai Institute of Biochemistry, China.

Huntington's disease (HD) is an autosomal dominant neurodegenerative disorder characterized by progressive involuntary movements and dementia^{1,2}. The symptoms of the disease, although devastating in severity, do not usually appear until the third to fourth decade of life. The gene defect is highly penetrant, and results in the loss of neurones in the basal ganglia, globus pallidus, and more diffusely in the cortex. A DNA marker, G8 (or D4S10), is tightly linked to Huntington's disease and this gene has been localized to chromosome 4 (ref. 3). The discovery of this linkage marker raises the possibility of developing a presymptomatic test for the disorder, and of eventually isolating the disease gene based on its map position⁴. We have now regionally localized the DNA marker G8 to the terminal band of the short arm of the chromosome, a region representing approximately 0.5% of the total human genome. The assignment was made by examining DNA from patients with Wolf-Hirschhorn syndrome, a birth defect resulting from partial heterozygous deletion of the short arm of chromosome 4.

Chromosome 4 contains approximately 6.55% of the total human genomic DNA. The search for additional DNA fragments near the HD gene and for the HD gene itself would be facilitated if the G8 marker were more precisely localized to only a small region of the chromosome. To achieve this goal, we used cells from patients afflicted with Wolf-Hirschhorn syndrome (WHS), a congenital anomaly involving heterozygous deletion of part of the short arm of chromosome 4 (4p-syndrome)^{5–7}. Victims of WHS are profoundly mentally retarded and have a characteristic craniofacial appearance including microcephaly, arched eyebrows, ocular hypertelorism, broad malformed nose, lobeless ears and micrognathia. The loss of chromosome 4 material can be the result of a *de novo* deletion, or due to inheritance of an unbalanced translocation, but most commonly involves the terminal 4p16 band⁷.

Initially, we obtained blood samples from six independent victims of WHS to establish permanent lymphoblastoid cell lines, and to prepare genomic DNA. A fibroblast line, GM0343, from a seventh WHS patient was obtained from the NIGMS

Fig. 1 Extent of chromosome 4 deletion in Wolf-Hirschhorn syndrome (WHS) patients. The region of chromosome 4 deleted in each patient, as determined by standard trypsin-Giemsa banding techniques, is shown. Note that the application of more sophisticated prophase banding methods could potentially detect differences between the deletions in patients A, B and C. The region containing the albumin locus is taken from ref. 17.

Human Genetic Mutant Cell Repository, Camden, New Jersey⁸. These patients presented a range of symptoms characteristic of WHS, and each had suffered an apparent terminal deletion of 4p. The extent of deletion in each WHS victim based on standard trypsin-Giesma banding is depicted in Fig. 1. In the case of patient D, the deleted 4p region had been replaced by an unidentified segment of another chromosome⁹. Although the size of the missing region was not identical in each case, all

patients were monosomic for at least band 4p16 which represents about 1/15 of the chromosome. For patients A, B and D, both parents were available for study. Blood samples could not be obtained from parents of the other cases. For patient A, an unaffected brother was also sampled.

The genetic linkage of G8 to HD was originally achieved using two restriction fragment length polymorphisms (RFLPs) detected by this probe in human genomic DNA digested with *HindIII*³. The informativeness of the G8 region as a genetic marker has recently been expanded by the cloning of adjacent genomic sequences and the discovery of additional RFLPs with the enzymes *BglI* (two sites), *EcoRI*, *PstI*, and *NciI* (ref. 10 and J.F.G., R.E.T. and R. A. Heft, manuscript in preparation). We reasoned that if the G8 locus mapped outside the deleted region, this could be demonstrated by detecting heterozygosity at any of these seven restriction enzyme sites. On the other hand, if the G8 region were deleted in a given individual, heterozygosity should never be observed. In addition, the apparent genotype of the WHS victim in such a case might be incompatible with the inheritance of one allele from each parent. We therefore performed Southern blot experiments with genomic DNA from each of the seven WHS patients, the three available sets of parents and the normal sibling of patient A. DNA was digested with each of the enzymes listed above, fractionated by agarose gel electrophoresis, transferred to a nylon filter and hybridized with appropriate probes known to reveal each RFLP. As a control, the DNAs were also typed for a *PstI* polymorphism at the albumin locus which maps below the centromere on chromosome 4¹¹. The results of this analysis are shown in Table 1.

Four of the seven WHS patients were heterozygous at the albumin locus indicating, as expected, that they were not deleted for this gene on the long arm of chromosome 4 and this polymorphism displays a level of heterozygosity of 49% in the general population. None of the seven patients was heterozygous at any of the RFLPs in the G8 region, although each of the normal parents was heterozygous for at least one of the seven sites. Table 1 also shows the level of heterozygosity displayed by each of these RFLPs in a random sample of 50 North Americans. Overall, 92% of unrelated individuals are heterozygous for at least one restriction enzyme site using this set of

Table 1 Phenotypes observed for RFLPs at the albumin and G8 loci

Individual	Cell line	Albumin locus <i>PstI</i>	G8 locus							Heterozygous at G8 locus
			<i>HindIII</i> (no. 1)	<i>HindIII</i> (no. 2)	<i>BglI</i> (no. 1)	<i>BglI</i> (no. 2)	<i>EcoRI</i> (no. 1)	<i>NciI</i>	<i>PstI</i>	
Patient A	GUS 2305	12	1	1	2	2	1	1	1	No
Father A	GUS 2302	12	1	1	1	2	2		12	Yes
Mother A	GUS 2303	12	1	1	12	2	1		1	Yes
Brother A	GUS 2304	12	1	1	1	2	12		12	Yes
Patient B	GUS 1548	12	1	1	1	2	1	1	1	No
Father B	GUS 1549	2	1	1	12	2	12		1	Yes
Mother B	GUS 1547	12	12	1	12	2	1		1	Yes
Patient C	GUS 1654	12	2	1	1	1	2	1	2	No
Patient D	GUS 2085	1	2	1	2	2	2	2	1	No
Father D	GUS 2225	12	12	12	2	2	2		1	Yes
Mother D	GUS 2224	1	12	12	2	2	12		1	Yes
Patient E	GUS 2098	1	2	1	1	2	2	2	1	No
Patient F	GUS 1553	12	1	1	2	2	2	1	1	No
Patient G	GM 0343	1	2	1	1	1	1	2	2	No
Heterozygosity		49%	46%	36%	46%	22%	58%	38%	16%	92%

Phenotypes for each RFLP were scored from the pattern of fragments observed on an autoradiogram after hybridization of Southern blots (containing genomic DNA digested with the indicated enzyme) to probes known to detect polymorphisms at either the albumin or the G8 locus (refs 3, 10 and J.F.G., R.E.T. and R. A. Heft, in preparation). Alleles are numbered 1 and 2 in order of decreasing size except in the case of *HindIII* site 2, where the order is reversed³. Heterozygotes at a particular site therefore have the phenotype 12. Heterozygosity in the general population, shown in the last line of the table, was calculated for albumin from ref. 16. For the G8 RFLPs, both individually and in combination, the table shows the level of heterozygosity observed in a random sample of 50 North Americans. All GUS cell lines are lymphoblastoid lines initiated in our laboratory for preparation of DNA³. GM 0343 is a fibroblast line purchased from the Human Genetic Mutant Cell Repository⁸.

Fig. 2 Deletion of the G8 locus in patient A. DNA from patient A, his brother, and both parents was digested with *Bgl*I and fractionated by agarose gel electrophoresis (0.8% agarose, 3 V cm⁻¹, 18 h). The DNA was transferred to Zetapor nylon membrane (AMF/Cuno) and hybridized to ³²P-labelled probe R7¹⁰. R7 is a phage clone containing a 16-kb fragment of chromosome 4 that partially overlaps with the G8 phage insert. Together, the two clones comprise approximately 29 kb of adjacent sequence from chromosome 4 (J.F.G., R.E.T. and R. A. Heft, in preparation). Fragments representing alleles 1 (2.0 kb) and 2 (1.9 kb) are indicated on the figure. All other fragments detected by the probe are invariant.

Fig. 3 Detection of hemizygosity for G8 locus by dosage. DNA (5 µg) from patient B, patient F, and the normal parents of patient B were digested with the enzyme *Hind*III and fractionated by electrophoresis on a 1% agarose gel. The DNA was transferred to Zetapor membrane and hybridized to ³²P-labelled pK082, a plasmid subclone of the G8 insert^{10,12}. This probe hybridizes to a single fragment of 3.7 kb in the size range examined. After autoradiography to detect the pK082 hybridization, the probe was removed from the filter by washing for 2 h at 65 °C in 0.01 × SSC (1 × SSC = 0.15 M NaCl, 0.015 M Na-citrate). The filter was then hybridized to ³²P-labelled pcHSA33-1, a human albumin cDNA clone¹³. This probe detects two fragments of 4.6 kb and 3.7 kb. Both probes detect additional fragments >10 kb in a *Hind*III digest, but these were not compared in these experiments due to difficulties in obtaining uniform transfer of large restriction fragments. The fact that both probes detect small fragments of similar size (3.7 kb) allows direct comparison of relative dosage without the ambiguities introduced by comparison of fragments that are very different in size.

seven RFLPs. The probability of picking seven individuals who are homozygous for all sites is therefore $(0.08)^7 = 2 \times 10^{-8}$. Thus, based on the lack of heterozygosity alone, it is likely that many or all of these WHS victims are in fact hemizygous at the G8 locus.

In patient A, the G8 locus has definitely been deleted from one chromosome (Fig. 2) as the child's DNA shows only the 1.9-kilobase (kb) *Bgl*I band representing the 2 allele. The genotypes of the father, mother and brother are 1 1, 1 2 and 1 1, respectively. Therefore, the WHS child is hemizygous at the G8 locus, having received a 2 allele from the mother with no contribution from the father. Hemizygosity at the G8 locus in patient A can also be demonstrated using the *Eco*RI RFLP (Table 1). For patients B and D where parental DNAs were also available, it was not possible to unequivocally demonstrate deletion of G8 by genotype alone. For these two, and for the patients with no available parents, we have compared the intensity of hybridization to sequences from the G8 region with that to a probe for albumin, which maps to the long arm of chromosome 4 (4q). Examples of these dosage experiments are shown in Fig. 3. A filter containing *Hind*III-digested DNA from patient B and his parents and patient F, was hybridized sequentially to pK082, a subclone of G8, and to pcHSA33-1, an albumin cDNA^{12,13}. *Hind*III was chosen for this experiment as both probes detect a fragment in the 3.7-kb range, thereby eliminating the possibility of artefact due to unequal transfer to the filter of DNA fragments of widely divergent sizes. In both patients, the intensity of hybridization of the albumin probe was approximately equal to that seen in the two normal parents. With G8, however, the intensity of hybridization was markedly reduced in the WHS children, indicating hemizygosity at the G8 locus. Similar experiments (data not shown) using *Hind*III and other restriction enzymes suggest hemizygosity at the G8 locus in each of the seven WHS victims. Ultimate confirmation of these results could be obtained by *in situ* hybridization experiments, or by segregating the deleted chromosomes in somatic cell hybrids. We are currently pursuing the latter strategy since it will generate cell lines with which new DNA probes can be quickly mapped to the vicinity of the HD gene.

The assignment of G8 to 4p16 does not dictate that the HD locus is also contained in this band. As the two are tightly linked,

however, at a distance considerably less than 10 centimorgans (10% recombination), it is likely that the HD gene maps to either 4p16 or to the distal portion of 4p15^{3,4,14}. More precise assignment of the HD gene will probably result from the isolation of another polymorphic DNA marker on the opposite side of the disease gene from G8. Such a flanking marker would make it possible to bracket the HD gene and physical mapping of the new marker relative to G8 would then give a precise position for the HD locus⁴. The isolation of a flanking marker is also essential for the development of an accurate presymptomatic and prenatal linkage test for HD¹⁵. With only the G8 marker, it is impossible to eliminate potential errors in diagnosis that would be caused by the recombination events that can occur between the HD locus and G8. Choosing DNA fragments at random from chromosome 4 has thus far been unsuccessful in providing the needed flanking marker. The mapping of G8 to the region deleted in WHS victims has presented a new, more efficient strategy. Segregation of the deleted chromosomes from WHS patients in somatic cell hybrids will provide the material necessary to rapidly screen new DNA clones to determine whether they map to 4p16, which represents only about 1/15 of the chromosome. Selective hybridization schemes based on these cell lines might also yield large amounts of DNA from this band, and provide a tremendous boost for efforts to clone and characterize the HD gene itself. Given the proximity of the G8 and HD loci, at least some of the WHS patients, especially patient F, must carry a deletion and therefore be hemizygous for the normal counterpart of the defective Huntington's disease gene. If the HD mutation causes the inactivation of a gene, these patients might be the functional equivalents of an HD heterozygote with a clinical picture clouded by the effects of other hemizygous loci. Since WHS victims rarely live to an advanced age and HD is normally a late-onset disorder, it is not possible to make such a conclusion at this time. Long-term follow-up and careful neurological examination of older WHS patients who have been tested for deletion of the HD gene by DNA analysis might certainly be warranted, as would attempts to obtain neuropathological information on this syndrome. If the HD mutation does not cause inactivation of the gene, hemizygosity at this locus might still contribute in some way to the symptoms of WHS. A resolution of this issue will probably await

the further characterization of both disorders at the molecular level.

Fission yeast *Schizosaccharomyces pombe* correctly excises a mammalian RNA transcript intervening sequence

Norbert F. Käufer*, Viesturs Simanis & Paul Nurse

Department of Cell Cycle Control, Imperial Cancer Research Fund Laboratories, Lincoln's Inn Fields, London WC2A 3PX, UK

Study of heterologous gene expression in the budding yeast *Saccharomyces cerevisiae* has shown that this organism is incapable of correctly removing intervening sequences from transcripts of higher eukaryotic genes¹⁻³. This is probably due to the stringent requirement for the presence of a TACTAAC box close to the 3' end of the intervening sequence if splicing in *S. cerevisiae* is to occur⁴⁻⁶. Comparison of the introns found in the fission yeast *Schizosaccharomyces pombe*⁷⁻¹⁰ has identified conserved sequences similar to those found in higher eukaryotes¹¹. Therefore, we have investigated whether *Schiz. pombe* is capable of accurately excising intervening sequences from the transcripts of higher eukaryotic genes. We show here that both the 5' and 3' splice sites of the simian virus 40 (SV40) small-T antigen transcript are accurately utilized when cloned viral DNA is expressed in *Schiz. pombe* cells. These data suggest that *Schiz. pombe* may be a better model system than *S. cerevisiae* for the genetic study of RNA splicing and for expressing higher eukaryotic genes.

The fission yeast *Schiz. pombe* is as convenient for molecular genetic analysis and gene manipulation¹² as the better-known budding yeast *S. cerevisiae*, but has been rather neglected in studies of eukaryotic gene expression. Recently it has become clear that *Schiz. pombe* genes generally have more introns than those of *S. cerevisiae* and that the conserved sequences in the vicinity of intron-exon boundaries are more similar to those found in higher eukaryotes. The consensus sequences found so far for *Schiz. pombe* introns are shown in Table 1. These are less stringent than those found in *S. cerevisiae*, particularly with respect to the TACTAAC box near to 3' splice sites, but are

Fig. 1 a, Construction of plasmid pNFK1. The structure of the SV40 early region mRNAs within the 1,169-bp *Hind*III B fragment of SV40 is shown. The nature of the probes used in this study is also indicated. In each case, the site of labelling is given first. The numbering system used is that suggested in ref. 13. Asterisks indicate sites of labelling. b, Structure of SV40 early region mRNAs. pDB248X DNA was digested to completion with *Bam*HI, treated with calf intestinal alkaline phosphatase to prevent self-ligation, and ligated to *Bam*HI-digested SV40 DNA. The ligation mix was used to transform competent *Escherichia coli* DH-1 to ampicillin resistance. Tetracycline-sensitive clones were identified by replica plating and the DNA extracted from the transformants and analysed by digestion with *Eco*RI to determine the orientation of SV40 DNA in the plasmid. Standard techniques²³ were used throughout. All enzymes were purchased from Boehringer Mannheim and used according to the manufacturer's recommendation. The arrow on the SV40 genome indicates the direction of transcription of the early region. The structure of pNFK1 is shown. Similar results were obtained with pNFK2 in which the orientation of the SV40 DNA is reversed.

very similar to those observed in higher eukaryotes. Given these similarities, it is possible that transcripts from higher eukaryotic genes may be correctly spliced in *Schiz. pombe*.

To test this possibility, we have introduced SV40 DNA into *Schiz. pombe* and investigated the splicing of the early region, which encodes the small-T and large-T antigens. The messenger RNAs coding for these two proteins are produced by differential splicing of a precursor mRNA. They share the same 3' splice site but use different 5' splice sites (ref. 13 and Fig. 1a). SV40 DNA digested with *Bam*HI was ligated into the *Schiz. pombe* shuttle vector pDB248X, and the resultant molecule, pNFK1 (Fig. 1b), was transformed into a *Schiz. pombe* *leu1-32 h⁻* strain

Fig. 2 S_1 mapping of 5' and 3' splice sites of SV40 early region transcripts in *Schiz. pombe*. **a**, Mapping of 5' splice sites using probe D. Lanes 1, 2, 10 μ g poly(A)⁺ RNA from cells transformed with pNFK1, S_1 digestion at 37 °C and 22 °C, respectively. Exposure was for 16 h at -70 °C with preflashed film and intensifying screen. M, DNA size marker consisting of Φ X174, digested with *Hae*III and 5'-end labelled with T4 polynucleotide kinase. **b**, Mapping of 5' splice sites using probe C. Lanes 1-3, 20 μ g, 15 μ g and 10 μ g, respectively, of total RNA extracted from SV40-infected CV-1 cells; lane 4, 10 μ g of poly(A)⁺ RNA from cells transformed with pNFK1. S_1 digestion was at 37 °C. Exposure was at -70 °C for 14 days with an intensifying screen. The arrow indicates the position of the 257-nt band. **c**, Mapping of 3' splice site using probe B. Lanes 1, 2, 10 μ g of poly(A)⁺ RNA from cells transformed with pNFK1. S_1 digestion was at 37 °C. Exposure was overnight at -70 °C with an intensifying screen.

Methods. RNA was extracted from cells in mid-exponential growth as follows. Cells were collected by centrifugation, washed once in ice-cold buffer A (50 mM HEPES-NaOH, pH 7.9, 5 mM EDTA, 150 mM NaCl) and resuspended in buffer A at $\sim 2 \times 10^9$ cells ml⁻¹. An equal volume of acid-washed glass beads (0.5 mm diameter; Sigma) was added and the cells broken by vigorous vortexing for 2 min. The liquid was removed to a fresh tube and the beads washed three times with buffer A. The combined lysate and washings were centrifuged briefly to remove cell debris and the supernatant fraction, adjusted to 1% (w/v) SDS and 100 μ g ml⁻¹ proteinase K (Sigma). After incubation at 37 °C for 30 min, the sample was extracted twice with phenol and chloroform, and precipitated with ethanol. Polyadenylated RNA was selected as described elsewhere²³ by two rounds of affinity chromatography on oligo(dT)-cellulose. DNA was extracted from SV40-infected CV-1 cells 72 h after infection at a multiplicity of 10 plaque-forming units per cell²³. S_1 mapping was performed essentially as described elsewhere²⁴. Annealing was overnight at 48 °C in 65% formamide, using 50 ng of probe, typically 20,000-50,000 c.p.m. Digestion was for 30 min at the indicated temperature using 400 U ml⁻¹ S_1 nuclease (BRL). 5'-End-labelled probes were prepared using T4 polynucleotide kinase following treatment with alkaline phosphatase. 3'-End-labelled probes were prepared using avian myeloblastosis virus reverse transcriptase. Standard techniques for labelling and subsequent gel purification were used²³. Samples were analysed on 0.3-mm-thick polyacrylamide gels²⁵ which were fixed and dried before exposure.

by selecting for *leu*⁺ prototrophic transformants. Polyadenylated RNA was prepared from a culture of one of these transformants in mid-exponential growth. A Northern blot of this RNA was probed with the 1.1-kilobase (kb) *Hind*III B fragment of SV40 which covers the early gene region (Fig. 1a). Transcripts hybridizing to this probe were detected, demonstrating that the transformants contained SV40 DNA and that the early region was being expressed. Transcript mapping suggested that they were being initiated at the SV40 early promoter. Some premature termination of transcription was also observed. No transcripts hybridizing to this probe were observed using RNA from cells transformed with pDB248X (data not shown). To determine if the SV40-specific transcripts were being correctly spliced, S_1 nuclease mapping experiments were undertaken.

In order to map the 5' splice sites of the transcripts, a 1,120-base pair (bp) *Ava*II/*Hind*III fragment was 3'-end labelled at the *Ava*II site using reverse transcriptase (Fig. 1a, probe D). Two fragments should be protected from S_1 digestion if both 5' splice sites are used, one of 484 nucleotides (nt) corresponding to the small-T transcript, and one of 204 nt corresponding to the large-T transcript. The predominant band observed is at 484

nt (Fig. 2a), demonstrating accurate use of the small-T antigen mRNA 5' splice site. However, no band was seen at 204 nt, suggesting that the large-T donor site is used very inefficiently, if at all. Some very weak bands of higher relative molecular mass (M_r) were also seen on prolonged exposure, consistent with the presence of a small amount of unspliced RNA. To confirm this result a second, shorter probe was used. A 432-bp *Hind*III/*Taq*I fragment, 3'-end labelled at the *Hind*III site, was prepared (Fig. 1a, probe C). Full-length probe should be protected if the small-T antigen 5' splice site is used. To test whether the large-T antigen 5' splice site is used at all, the autoradiograph was overexposed to see if the predicted 257-nt band could be observed. Many weak bands became visible, one of which was 257 nt long; this band co-migrated with a protected fragment corresponding to the large-T antigen mRNA 5' splice site obtained using RNA extracted from SV40-infected CV-1 cells (Fig. 2b). This suggests that the large-T antigen mRNA 5' splice site may be used, although at an extremely low level.

To map the 3' splice site, which is common to transcripts of both large-T antigen and small-T antigen, a 810-bp *Ava*II/*Fnu*4HI fragment, 5'-end labelled at the *Hind*III site, was used as a probe (Fig. 1a, probe B). A 260-nt fragment was protected from S_1 -nuclease digestion (Fig. 2c), indicating that the 3' acceptor site is accurately used by *Schiz. pombe*. In addition to the 260-nt band, another, less intense band at 810 nt was observed corresponding to protection of full-length probe. This may be due to DNA-DNA reannealing or to a fraction of the transcripts not being processed. Correct use of the 3' splice site was confirmed using a *Hind*III/*Ava*II fragment 5'-end labelled at the *Hind*III site (Fig. 1a, probe A), when the expected protected fragment of 570 nt was observed (data not shown).

To determine whether the large-T or small-T antigen proteins were being synthesized, a Western blot of protein extracted from *Schiz. pombe* cells transformed with either pDB248X or pNFK1 was probed with pAb419 (ref. 14), a monoclonal antibody which recognizes an epitope found in the N-terminal region common to both proteins. Synthesis of the 20,000- M_r small-T antigen was clearly detectable in cells transformed with pNFK1 (Fig.

Table 1 Conserved sequences at intron-exon boundaries

	5' Splice site	Internal conserved sequence	3' Splice site
Higher eukaryotes	G GTAAGT G	CTAAT G C	TAG
<i>Schiz. pombe</i>	G GTANGT	CTAAT G C	TAG A
SV40 large-T	G GTATTT	CTAAT	TAG
SV40 small-T	G GTAAAT	CTAAT	TAG

The consensus for *Schiz. pombe* was derived from refs 7-10, 22 and that for higher eukaryotes from ref. 11. The SV40 sequence was taken from ref. 13.

Fig. 3 Western analysis of proteins synthesized in *Schiz. pombe* transformants. Lane 1, 10 ng of purified SV40 large-T antigen; lane 2, protein extracted from cells transformed with pDB248X; lane 3, protein extracted from cells transformed with pNFK1. The numbers indicate the positions of marker proteins ($M_r \times 10^{-3}$).

Methods. *Schiz. pombe* cells transformed with the indicated plasmids were grown to a cell density of 5×10^6 cells ml^{-1} in minimal medium. The cells were collected by centrifugation, washed once in phosphate-buffered saline and broken by vortexing with glass beads. The broken cells were boiled in sample buffer²⁶ for 2 min. Cell debris was then removed by centrifugation, and the protein extracts were loaded onto a 5–15% (w/v) polyacrylamide gel²⁶. After electrophoresis the protein was transferred to nitrocellulose²⁷. The blot was hybridized with pAB419 (ref. 14) as described elsewhere²⁸. After washing, bound antibody was detected using ¹²⁵I-protein A (Amersham). The blot was autoradiographed using preflashed film and an intensifying screen at -70°C .

3). However, even on prolonged exposure, no large-T antigen was detected, a result consistent with the observed splicing pattern of the SV40 early region transcripts made in *Schiz. pombe*.

These results demonstrate that *Schiz. pombe* can correctly recognize the 5' and 3' splice sites of the SV40 small-T antigen pre-mRNA. The correct 3' splice site is not recognized in the budding yeast *S. cerevisiae* and the 5' splice sites utilized only very inefficiently¹⁵. In *Schiz. pombe* the 5' splice site used to produce the large-T antigen mRNA was used very inefficiently, if at all—an unexpected result, since in lytically infected monkey cells the large-T antigen 5' splice site is used two to three times more frequently than the small-T antigen 5' splice site¹⁶. This could be due to the difference in sequence between the SV40 large-T antigen 5' splice site and the *Schiz. pombe* consensus sequence (Table 1). None of the *Schiz. pombe* introns sequenced to date has a thymine at nucleotide 5 at the 5' end. Alternatively, it is conceivable that although *Schiz. pombe* can recognize higher eukaryotic splicing signals, it cannot cope with multiple 5' splice sites for a single 3' splice site. Thus, having identified the 3' splice site, perhaps through an interaction with the internal conserved sequence, the *Schiz. pombe* cell may scan through the transcript until it identifies the first 5' splice site and completes intron excision. A second 5' splice site beyond this would then be used inefficiently, if at all. In the SV40 system, this possibility is readily testable using the $\Delta 54$ –59 mutants of SV40¹⁷, in some of which the small-T antigen 5' splice site is deleted.

Another observation which may be relevant to this phenomenon is the report that *Xenopus* oocytes use only the small-T 5' splice site when SV40 genomes are co-injected with antibodies against ribonucleoprotein particles¹⁸. This observation suggests that the two 5' splice sites may have different properties. It is thus possible that use of the large-T 5' splice site may have a different requirement for ribonucleoprotein particles from that of the small-T 5' splice site which cannot be provided by the heterologous *Schiz. pombe* cells.

This is the first report of a higher eukaryotic intron being correctly spliced in yeast. Although it may initially seem odd that fission yeast should behave so differently from budding yeast, it should be remembered that these two organisms, although both ascomycetes, are not closely related. Recent sequence comparisons suggest an evolutionary divergence which could be as much as 1,200 Myr¹⁹. There are also differences in their promoters²⁰ and in aspects of the mitotic cycle such as the

presence of a G_2 period and chromosome condensation²¹. In all cases, the behaviour of *Schiz. pombe* is closer to that of higher eukaryotes than is *S. cerevisiae*. For these reasons we suggest that *Schiz. pombe* should be considered more seriously as an organism for expressing higher eukaryotic genes and for genetic analysis of eukaryotic splicing.

We thank ICRF for financial assistance, EMBO for a short-term fellowship awarded to N.F.K., and our colleagues in the Cell Cycle Control Laboratory for helpful discussions.

Sedimentary microrhythms

WITH regard to the interesting article by House¹ in which sedimentary microrhythms from marine Jurassic strata of southern England were investigated, the following may be of additional interest.

House assigned 60 ammonite zones to the Jurassic period, of which two were referred to the non-marine Lulworth Beds (Purbeck Beds). In the Purbeck Beds of Dorset and the Weald 39 cycles have been identified among the ostracod faunas which Anderson and Bazley² have termed faunicycles. One faunicycle comprises an alternation of two ostracod assemblages: (1) species identified as tolerant of relatively saline waters (S-phase); (2) species tolerant of brackish to almost freshwater conditions (C-phase). The ostracod genus *Cypridea* dominates the C-phase of the faunicycles. The number of ammonite zones (among other biostratigraphical tools) allocated to the Lulworth Beds (without ammonites) will ultimately depend on the positioning of the internationally agreed base of the Cretaceous period. In southern England the Cinder Bed Member is generally accepted as the base of the Cretaceous although recent work questions some assumptions³⁻⁵. For the calculations here the Cinder Bed faunicycle² is taken as representing the base of the Cretaceous.

If the Lulworth Beds are accepted as representing two ammonite zones, Table 1 shows values for the average length of a faunicycle (based on 20 faunicycles). The assignment of two ammonite zones to the Lulworth Beds may prove to be inaccurate and lead to re-interpretation of the values shown (for example, one ammonite zone for 20 faunicycles would give averages approaching the obliquity figure; M. R. House, personal communication). Anderson and Bazley² considered that if the faunicycles were climatically induced, the precession of the equinoxes might have been responsible.

Sedimentary microrhythms can be recognized in the Lulworth Beds, and evidence of possible annual seasonal rhythmites can be seen in the deposits of restricted pools (Lower Dirt Bed of central Dorset) and also expressed in the pattern of fossil tree-growth rings⁶. There is much sedimentary variation in the Purbeck Beds due to their deposition marginal to a lagoon of fluctuating water level⁷.

The faunal cyclicity of the Purbeck Beds reflects palaeoecological cyclicity that is

not mirrored by lithological microrhythms. Is it coincidence that this cyclicity averages 117 kyr, assuming the Jurassic to be 70 Myr in duration? Is this an expression of the 100-kyr cycle due to orbital forcing⁸? Ostracod assemblages have allowed correlation across north-west Europe in the late Jurassic and early Cretaceous⁹, consisting of groups of ostracod zones and faunicycles. The faunicycles are assemblages of ostracod species; not purely evolutionary sequences, they represent changes in palaeoenvironment and may be laterally variable in their specific content². The fact that the faunicycles persist over rapid lateral and vertical lithological/environmental changes suggests the involvement of some longer-term factors in the cyclicity. Might it be the case that, in palaeoenvironmental settings where sedimentary microrhythms are not manifestly obvious, such as in the marginal-marine Lulworth Beds of Dorset, biotic rhythmicity (ostracod faunicycles) reflects climatic cyclicity due to orbital forcing?

Note added in proof: Anderson¹⁰ has recognized one more faunicycle in the Purbeck Beds. Following assumptions made above the average faunicycle length is 111 kyr.

Pre-Rhaetic therian mammals

THE discovery of a *Kuehneotherium* tooth in deposits older than the Rhaetic transgression in Somerset, UK, was reported by Fraser, Walkden and Stewart¹, who claim that it is the oldest record of a therian mammal, predating the *kuehneotheriids* from the supposedly 'Rhaetic' locality of Saint-Nicolas-de-Port in eastern France, described by Sigogneau-Russell². However, one of us has recently studied the amphibian and reptile remains collected at Saint-Nicolas-de-Port by G. Wouters and P. Coupatez, and has compared this faunal assemblage with those from better known German localities³. This reveals that the Saint-Nicolas-de-Port fauna is of roughly the same age as that from Kuhn's levels 15-20 of the Halberstadt locality⁴, and should thus be referred to the Norian.

Therefore, the Emborough *Kuehneotherium* and the mammals from Saint-Nicolas-de-Port may actually be of the same age, and may all qualify as the oldest known mammals.

The case of the Saint-Nicolas-de-Port locality illustrates the fact that the Rhaetic stage is of very doubtful value as far as continental faunas are concerned. The Rhaetic was first defined as the top of the marine Triassic in the northern Alps, but even there its validity has been questioned, as its fauna is not significantly different from that of the Norian, so that many stratigraphers have abandoned it altogether⁵. Outside the Alpine domain, the term Rhaetic is even less meaningful, especially in the Germanic domain where correlations are difficult. It seems to be impossible to define a typically Rhaetic vertebrate fauna, and vertebrate localities lumped together in the so-called Rhaetic may be of very different ages. We are therefore in full agreement with the opinion expressed by Fraser, Walkden and Stewart¹ that the Emborough find 'throws doubt on the fundamental distinctiveness of pre-Rhaetic and post-Rhaetic vertebrate faunas'. Continued use of the terms Rhaetic and Rhaetic in a stratigraphical sense causes more problems than it solves, and cannot contribute to a better understanding of the relative stratigraphical position of late Triassic continental vertebrate localities.

FRASER, Walkden and Stewart¹ have recently announced the discovery of fossil mammal teeth in a terrestrial fissure deposit at Emborough in the Mendip Hills (Somerset, UK). It has been dated by them as 'pre-Rhaetic' following Robinson⁶ who, in the then absence of direct palaeontological dating, invoked comparisons based on rock types, topographical position and the general nature of the faunal assemblage. We disagree with this.

Robinson's use of rock types for dating is inappropriate, since fissure fills and normal stratified sequence are of markedly different origin. The marl lithologies cited by Fraser *et al.*¹ as typical 'pre-Rhaetic' are also known from the 'Upper Rhaetic'³.

We envisage a situation where, in the prolonged period of sub-aerial exposure before, or during, the early Rhaetic, tectonic and solution features formed which

Table 1 Average length of a faunicycle

Duration of Jurassic (Myr)	Duration of each zone (Myr)	Average faunicycle length (kyr)
60	1.00	100
65	1.08	108
70	1.17	117
75	1.25	125

contained little sediment. As sea levels rose during the Rhaetian, these fissures filled with contemporaneous sediment, with additional solution occurring during intermittent periods of local Rhaetian sub-aerial exposure⁴.

When Robinson² dated the Emborough fissure as Norian she was influenced by the absence of mammals, so that their discovery removes this age connotation. Fraser *et al.*¹ distinguish a discrete Norian fauna, in spite of the lack of an independent Norian date for this supposed pre-Rhaetic reptile assemblage, and in disregard of the evidence from the Tytherington fissure⁵ which is dated as Rhaetian using diverse microfloras. Fraser *et al.*¹ dismiss this date, indicating incorrectly that these particular deposits were tectonically disturbed and mixed. Microfloras of Rhaetian age have now been recovered⁶ from six separate fissure fills in Tytherington Quarry and except for one minor slump sequence none of these palynomorph-bearing intervals shows any evidence of tectonic mixing. Whilst some of the Tytherington fissures were tectonically initiated⁶, most show a pre-infill solutional influence or are entirely solutional in origin. In addition to microfloras, five of these fissures also contain fish (including *Pholidophorus*, *Gyrolepis*, *Hybodus*, *Saurichthys*) and crustacea (*Euestheria minuta*) characteristic of the Rhaetian⁶. The microflora and fauna both occur in the same matrix as the supposed pre-Rhaetic Norian reptile assemblage.

Because the Tytherington 'Norian' reptile fauna has been shown to be Rhaetian and because the nature of Robinson's evidence for a pre-Rhaetic age at Emborough is highly equivocal, we suggest that the presence of *Kuehneotherium* could more reasonably indicate the date of the Emborough deposit than vice versa. It is generally accepted that the abundant mammal fossils (including *Kuehneotherium*) from other British fissure fills are of Rhaeto-Liassic age⁷. We therefore place the Emborough deposit in the Upper Rhaetian and see no justification for the date proposed by Fraser *et al.*¹.

We thank Derek Moore for critically reading the manuscript.

FRASER, WALKDEN AND STEWART
REPLY—We are most interested to learn that on the basis of detailed comparisons

with well-dated German faunas¹, Buffetaut and Martin would now revise downwards the age of the Saint-Nicholas-de-Port vertebrate assemblage. Although there is as yet no other firm evidence to confirm a Norian rather than Rhaetian age for these late Triassic deposits, the presence of *Kuehneotheriids* amongst otherwise acceptable Norian forms does suggest a mammalian occurrence as old as the Emborough *Kuehneotherium* specimens.

As stressed by Warrington *et al.*², the term 'Rhaetic' in Britain is a lithostratigraphic one, not to be confused with the chronostratigraphic stage name 'Rhaetian' which generally extends a little lower. The marine incursion which established characteristic Rhaetic deposits in Britain was a rapid event affecting wide areas almost simultaneously³. It thus provides a useful stratigraphical marker, and it would be difficult to persuade geologists not to use it. Hitherto, all records of late Triassic mammals have post-dated this transgression, but at Emborough, where we have found mammal remains for the first time, the isolated Triassic pocket containing them lies beneath a planation surface associated with Rhaetic (Westbury Formation) sediments. The pocket sediments themselves are completely distinct, and have continental characteristics identical with Norian deposits nearby. We fully agree that in many other places, including parts of mainland Europe, such a distinction could not so clearly be made.

Meanwhile, Whiteside and Marshall claim, on the basis of their own interpretation, that the Emborough deposit in which we have found mammalian teeth is probably of Rhaetian rather than Norian age. Our dating of the deposit followed careful re-assessment in the field as part of a wider study of the fissure deposit phenomenon, and our acceptance of Robinson was arrived at because we found no cause to criticize Robinson's evidence. Certainly, if palynological evidence came to light, the deposit could prove to be Rhaetic, but equally it might be pre-Norian or mid-Jurassic.

The evidence for a pre-Rhaetic age is based on classical stratigraphical argument, reviewed by Whiteside and Marshall, and no evidence to the contrary has emerged. The deposit is in fact closely similar to local Keuper Marl facies and is comparable to pre-Rhaetic boulder and conglomerate deposits elsewhere in the Mendips. It contains no evidence of derived Rhaetic or post-Rhaetic sediments (including the ubiquitous phosphatic basal bone-bed formerly exposed nearby within Emborough Quarry) and is unlike any of the known post-Norian lithologies in the area. If Whiteside and Marshall believe that the deposit belongs to the Upper Rhaetian, then the onus of proof lies with them and we will welcome any new information they can provide.

As regards the dating of the Tythering-

ton deposits, we merely wish to sound a strong note of caution at a locality where the fissures owe their origin to tensional stresses which continued into the Rhaetic. Whether directly attributable to tectonic dilation, or resulting from meteoric re-working or marine flooding of open systems (for example, ref. 4) the effects of remobilization, mixing and contamination can be very subtle. We would not dispute that the fish faunas may be of Rhaetian age, but it would be helpful if the full sedimentological and faunal details of Tytherington were published in order to provide a firmer basis for discussion. However, the age of the Tytherington assemblages has no direct bearing on the age of the Emborough mammal find, and we raised the matter originally because if it does prove to be Rhaetic it further supports our contention (misunderstood by Whiteside and Marshall and by the author of ref. 5) that there is no longer any case for a fundamental distinction between the terrestrial faunas before and after the Rhaetic transgression based on the presence or absence of mammals.

Flow law for ice in polar ice sheets

DOAKE and Wolff¹ have argued that a relationship between strain rate $\dot{\epsilon}$ and stress τ of the form $\dot{\epsilon} = A\tau^n$ with $n = 1$, rather than the commonly used value of 3 (and where A is the flow law constant), provides a better fit to data from polar ice masses. Weertman² has discussed the implications. I remain unconvinced for the following reasons.

(1) The Devon Ice Cap borehole is within a distance of 3 ice thicknesses from the ice divide. Modelling of flow near divides, with $n = 3$, shows that the shape of the velocity-depth profile changes with distance; tilting data, if analysed by Doake and Wolff's method, would give a value of n increasing from zero near the divide to 3 at about 10 ice thicknesses from it³. Doake and Wolff's analysis is therefore invalid.

(2) At Camp Century, the strain rate measured for $\tau_{xz} = 10$ kPa, where x_L^* and 3 define a rectangular coordinate system, is less than the observational error⁴. The same is almost certainly true at Law Dome.

* Present address: Department of Zoology, University of Cambridge, Downing Street, Cambridge CB2 3EJ, UK.

Doake and Wolff's diagrams suggest that removal of this point would increase n to ~ 2 in both cases.

(3) The Amery Ice Shelf data lie on the line for $n=3$, not $n=1$.

(4) The measured spreading rate of Ward Hunt Ice Shelf ($\dot{\epsilon} = 3.3 \times 10^{-12} \text{ s}^{-1}$, $\tau = 12 \text{ kPa}$)^{5,6}, not mentioned by Doake and Wolff, lies between the lines for $n=1$ and 3. A significant fraction of this ice shelf consists of old sea ice, so its impurity content will be high. Because soluble impurities 'soften' ice, correction for this would move the data point towards the line for $n=3$. It has been suggested that the ice shelf may be grounded beneath the survey site, in which case the analysis would not apply. I believe that grounding can be ruled out because the surface slope is of the magnitude ($1.6 \times 10^{-3} \text{ rad}$) expected on floating ice⁵, and the slope is towards the Ward Hunt ice rise⁵; it would be in the opposite direction if the site were on the ice rise.

(5) Holdsworth⁷ suggested why the low-stress points from Erebus Ice Tongue deviate from the line $n=3$; crevasses penetrate a significant fraction of the thickness in the outer part and effectively soften the ice. This seems plausible to me.

(6) New data⁸ from Ross Ice Shelf give $n=3.3$.

(7) Surface velocity measurements^{9,10} on ice rises give values of n of 3.13, 3.7 and 4.2 over the stress range 50–130 kPa.

Doake and Wolff believe that borehole tilting is affected by transient creep because flow changes the depth of, and thus the shear stress on, an ice particle. Weertman suggested that this might make the flow law appear linear. This effect should be greatest in the ablation area of a temperate (0°C) glacier; the vertical velocity there is an order of magnitude greater than in polar ice sheets. Moreover, accumulation and ablation change the ice thickness seasonally by about 5 m. However, tilt measurements¹¹ in 12 boreholes in temperate glaciers provide convincing evidence that n lies between 3 and 4.

Measured velocity-depth curves vary widely in shape, even after allowance is made for temperature variations. I believe that differences in longitudinal stresses, which affect the shear strain rate only if the flow law is nonlinear, can account for much of the variation.

DOAKE AND WOLFF REPLY—Our position regarding the flow law for polar ice¹ (relating strain rate $\dot{\epsilon}$ and stress τ by $\dot{\epsilon} = A\tau^n$) is consistent with Lliboutry and Duval², who comment that "any attempt to determine the creep law of polycrystalline ice is illusory". Because factors such as crystal size and fabric, and impurity content appear to have a major role in determining the deformation of polycrystalline ice, and because these factors cannot, at least at present, be deduced or modelled *a priori*, there seems to be little point in using a complex flow law that requires large but unknown *ad hoc* corrections to be made to fit experimental data. Our approach has been to find the simplest relationship between observed strain rates and deduced stress field that produces the greatest degree of harmony and the lowest range of 'enhancement factors' between different data sets. It is also reassuring to note that Lliboutry and Duval² have independently concluded that, for the Holocene ice at Byrd Station, a linear flow law gives the best fit to field-tilting data.

As to the points raised by Paterson:

(1) Raymond's³ model of flow near ice divides shows that for $n=1$, there is no difference in the velocity profile shape with distance from the divide. An $n=1$ exponent gives a good fit to Paterson's observed velocity-depth profile at Devon Island, while $n=3$ with Raymond's model applied to Devon Island gives a poor fit⁴.

(2) There is common agreement that borehole data are difficult to analyse because of measurement errors and uncertainties. Discarding the point at 10 kPa at Camp Century would in any case lead to a value of $n=1.47$. There is no justification for discarding the point at Law Dome. The measured strain rate (before our adjustment to -28°C) is well above any likely observational error. (The data at Law Dome must in any case be constrained by the requirement of non-negative basal velocity, which led to the two circles (not used in the regression) at the high stress end of our Fig. 2d. Lliboutry and Duval² have produced more detailed arguments about factors affecting flow in boreholes, but we reiterate that if $n=3$ is used, such large variations in A (the flow law constant) are required to fit data that the flow law ceases to have any predictive value.

(3), (4) The analysis by Thomas⁵ of ice shelf data assumed that resistive forces due to shear stress gradients could be ignored. This is not true for either Amery Ice Shelf (where also the site was "situated on a small hill"⁵) or Ward Hunt Ice Shelf (where also grounding may "extend beneath the site"⁵). In reply to the letter by Hattersley-Smith⁶, we do not read Weertman's comments as saying that our data go against a linear creep law.

(5) The only data available from an ice shelf which approaches the ideal

'unbounded' state are those from Erebus Glacier Tongue⁷. It seems unnecessary to postulate a 'softening' of the ice by crevasse penetration, which in any case still does not bring the data to the line $n=3$.

(6) The back-stress pattern⁸ on the Ross Ice Shelf was inferred from an otherwise untested theory of crevasse formation on the underside of ice shelves. Data are sparse and Jezek⁸ has reported discrepancies of up to 1 bar with values of back stress calculated by other methods⁹. Measurements of strain rate and crevasse height were made at different sites, meaning that interpolations had to be made¹⁰. No allowance for temperature variations have been made^{8,10} although this could "represent an approximately threefold variation in the strain rate" (ref. 9) for $n=3$. There is a large scatter in the data of Jezek and others¹⁰, even for the points selected as representing 'best data'. Although this is an intriguing use of unusual experimental data, we do not regard the values as being sufficiently accurate for defining a flow law.

(7) We specifically excluded discussion of ice rise measurements because of the approximate nature of their analysis.

The penultimate paragraph broaches the point that n appears to lie between 3 and 4 for temperate ice. We specifically confined our remarks to polar ice and did not consider temperate ice because of the problem of accounting for free water in the flow law². Because of this water, we see no reason why temperate and polar ice should have similar flow laws.

The final paragraph mentions velocity-depth curves in boreholes. We have shown that if measured temperature profiles are taken into account, better agreement is reached with $n=1$ than $n=3$ in polar ice. There are still discrepancies, which may be due to unmodelled factors such as impurity content or crystal size and orientation; these discrepancies are much reduced for $n=1$. We explicitly allowed for longitudinal stresses in the analyses represented by our equation (1) (ref. 1), but there are no data on their variation with depth. Again, we conclude that on evidence available it is not necessary to use a nonlinear flow law to describe the flow and deformation of polar ice sheets.

NEW WAVE FOR CELL CULTURE

Type I Collagen (Bovine dermis)

CELLMATRIX I (Acid soluble collagen)

CELLMATRIX II (Pepsin solubilized collagen)

Type IV Collagen (Anterior-capsule of Bovine crystalline lens)

CELLMATRIX IV

Characteristics

- *Sterilized solution of highly purified collagen
- *Directly used for cell culture
- *High reproducibility

Useful for

- *Coating of cell culture material surfaces
- *Collagen gel matrix culture

Growth of mouse mammary tumor cells embedded in collagen gel matrix. (Cultured for 2 weeks in collagen gels reconstituted from CELLMATRIX I).

JOURNAL OF CHEMOMETRICS

EDITOR-IN-CHIEF

Professor Bruce R. Kowalski

Department of Chemistry, University of
Washington Seattle, Washington 98195, USA

ASSOCIATE EDITOR — EUROPE

Dr. Bernard G.M. Vandeginste

Department of Analytical Chemistry, Faculty of
Science, Catholic University of Nijmegen,
Nijmegen, The Netherlands

ASSOCIATE EDITOR — NORTH AMERICA

Professor Steven D. Brown, Department of
Chemistry, Washington State University,
Pullman, Washington 99163, USA

AIMS AND SCOPE

Chemometrics is now emerging as a significant discipline in its own right and is increasingly important as a research tool, particularly in analytical chemistry. There is a growing emphasis on information management in the laboratory.

Chemometrics is applied to extract useful information from experimental data, and is being used to develop strategies for optimal decision making at all levels (laboratory organisation, experimental method design and selection).

The specific aim of the journal is to publish papers on both fundamental and applied aspects of chemometrics, and to provide a forum for the exchange of information on meetings, etc. for the growing international chemometrics research community. It is envisaged that regular short, critical review papers will be a particularly important feature of the journal, since the readership at which it is aimed is multidisciplinary. As chemometrics is a science that bridges chemistry and applied mathematics and statistics, we intend to create the journal as an invaluable aid to researchers and educators in all three areas. The journal will also provide a facility for the exchange of software and the publication of computer programmes. The scope of the journal will include the following topics:

Pattern recognition • Multivariate analysis, including factor analysis • Optimisation strategies • Signal processing • Sampling strategies and sampling handling • Curve fitting and data reduction • Artificial intelligence • Parameter estimation • Applications of operations research, e.g. graph theory and digital simulation • Calibration • Spectral library searching • Image Analysis • Intelligent instrumentation • Decision making • Information theory • Regression analysis • Modelling • Cluster analysis • Interactive graphics • Interplay between computers and chemometrics • Information management • Robotics

The following application areas would be covered

Chromatography • Spectroscopy • Surface Analysis • Clinical Chemistry • Food Science • Electrochemistry • Process Control • Environmental Chemistry • Biomedical Research • Geochemistry

Scan the gel horizon with HOEFER!

- Stained, wet gels
- Autoradiograms and other negatives
- Western blots
- TLC plates
- Dot and slot blots

Hoefer's Scanning Densitometer (GS 300) scans them all and it costs thousands of dollars less than most other Densitometers.

Why? Because the GS 300 is a streamlined, single wavelength instrument designed for a particular laboratory use: *the rapid and sensitive screening of electrophoretic separations resolved on gels, papers and films.* Easily attached to the recording device that best suits your purposes—chart recorder, integrator or computer—the GS 300 is a *trim, basic unit suitable for nearly all laboratory scanning tasks.* Yet for all its simplicity, its performance is exceptional. Its features include:

- An incredibly stable 580 nanometer LED light source. Regulation is better than $\pm 0.5\%$. Output is 100 millivolts per OD unit at the lowest gain setting; and 1 volt per OD at the highest.
- A 250 micron fixed slit that gives outstanding resolution.
- Two operational modes—transmittance and reflectance—that enable you to scan any medium, transparent or opaque, stained with visible dyes.
- Dual scanning speeds that allow you to scan a 20 cm gel in $1\frac{1}{2}$ or 3 minutes.
- Compactness for easy portability and storage. The GS 300 measures $18" \times 10\frac{1}{2}" \times 5"$ and weighs less than 10 lbs.
- Even complete with our Densitometry Software Package, the Hoefer Scanning Densitometer costs a fraction of what most other densitometers cost.

And now, analyze and store scans with Hoefer's brand new **Densitometry Software Package**

With this sophisticated program you can:

- Store scans (with or without base lines adjusted)
- Integrate scans
- Determine molecular weight
- Determine R_f 's

You can use our densitometry software with your IBM-PC, or your Apple II+ or IIe, and the appropriate printer. All you do is plug in the A to D converter that comes with the package and you're ready to go.

HOEFER SCIENTIFIC INSTRUMENTS

Cell populations re-examined

from R.F. Jarvis and D. Rossington

Cell biology has been in existence for over 400 years. But only recently has it been possible to study cells in massive numbers.

"... these pores, or cells, were not very deep, but consisted of a great many little boxes ..."

I no sooner discern'd these, which were indeed the first microscopical pores I ever saw, and perhaps that were ever seen ... but methought I had with the discovery of them, presently hinted to me the ... reason of all the Phaenomena of cork; ..."

(Robert Hooke, 1665)

AND so an era began. The basic living unit of plant, animal and man, had been seen and identified. With the Dutch draper Leeuwenhoek's observation, at about the same time, of a central body within salmon blood cells, such observations heralded the beginnings of modern cell biology.

Within the confines of a tiny space (the average mammalian cell is some 15–20 μm in diameter) is a completely automated, computerized factory possessing an organizational capacity to direct the reproduction of cells into masses of tissues with unique tasks, so that a complete body can be built from a single isolated cell.

The living cell may appear fairly simple on the surface but microscopists have long recognized internal structures. The most prominent of these structures, the nucleus, houses the chemical templates of production, the chromosomes. The nucleus is suspended in cytoplasm, a rich fluid containing many complex molecules and many small organelles, and the whole is contained within an outer cell wall, the membrane.

Soon after fertilization the ovum begins to divide continuously to form a mass of

Fig. 2 A typical flow cytometer, using scattered light to determine cell characteristics.

smaller, similar cells. Within this mass of cells, or blastocyst, new cells are produced, and soon the three basic tissues of the fetus — the ectoderm, mesoderm and endoderm — emerge. The layers become entwined and growth continues, with the ectoderm further specializing to produce the skin and nervous system while the liver, pancreas, lungs and other organs, plus the digestive tract, spring from the primitive endoderm. Muscle, blood, bone and the connective tissues will result as the mesoderm divides and specializes.

Depending on the function of the tissue from which a cell is extracted, cells will vary in outer size, shape and internal organization. By studying the morphological and biochemical profiles of the cells, biologists can ascertain the family tissue and, often, whether the cell is healthy.

Methods of examining and classifying cells go back many years. The chemical and physical structures of the cell are routinely viewed after suitable processing to stain the various constituents with a range of organic dyes. Solid tissues are sliced by a sharp knife, or microtome, after the tissue has been held firmly embedded in a wax block or frozen solid. Then, the one-cell-thick section is coated onto a glass slide and stained. Many stains exist to show the presence of the internal structures of the cell and of particular cellular enzymes and both internal and external excretions.

The examination of blood to identify and count the red cells, white cells and platelets has found increasing importance as electrical methods have increased the precision and usefulness of such tests.

Most patients seeing doctors and entering our hospitals routinely have a full examination of their blood to aid in the diagnosis and treatment of their ailments. Apparatus exists to count and size, rapidly and routinely, the main types of blood cells. Blood specimens can be measured at rates of over 100 per hour, and data presented include the haemoglobin content as well as the concentration of several subpopulations of white cells. One such apparatus is shown in Fig. 1.

A new ability to study subpopulations of blood cells and suspensions of dispersed solid tissues has recently been developed, allowing cell surface molecules to be identified. The surfaces of circulating blood cells are not smooth but have many molecules projecting from them. The white blood cells are a vital part of the human immune system that defends us against the challenge of microorganisms which threaten to destroy us in order to live themselves. Although the main types of white blood cells can be routinely distinguished by morphology using manual staining, or automatically counted on a blood cell counter, our understanding of them and hence of the immune system has leapt forward in recent years because of the development of reagents which can identify parts of the cell surface molecules. With these monoclonal antibody reagents it has been possible to divide the white cell population responsible for specific immunity (the lymphocytes) into various subgroups based on the different molecules (or antigens) present on their surface. The complex task of correlating these subgroups according to function and

Fig. 1 An automated blood cell counter.

Fig. 3 The distribution of lymphocytes, monocytes and granulocytes displayed from simultaneous measurements of forward angle light scatter and wide angle light scatter as recorded by a flow cytometer, measuring 2,000 cells per second.

role is far from complete but this technique has already led to a better understanding of the various diseases of the immune system.

The circulating blood cells are also studied by haematologists who use commercial monoclonal antibody reagents in the same cell surface techniques to type and count the various immature or mature cells that are present in leukaemia and lymphoma. Here again, the ability to identify subpopulations has led to better diagnosis and monitoring of these tumours of the blood. Modern instruments, called flow cytometers, are now available that will examine many thousands of individual cells each second, and report on their characteristics. A typical flow cytometer is shown in Fig. 2. The cells in suspension are made to follow a confined trajectory through a very intense beam of light. Light is scattered from a cell entering the beam and transmits vital information to sensitive detectors concerning the size and constitution of the cell (as for example, in Fig. 3). Additionally, probes which fluoresce in the bright light can be used to identify particular antigens and other cellular constituents.

New methods in the field of cellular biology will emerge in the future. Pattern recognition computers are already able to evaluate a stained section much as a human does but, at present, are relatively slow. New identification probes will be devised to look inside the cell and evaluate its integrity. Understanding the functions of specialized cells, in relation to those surrounding them, will become increasingly important. The search for knowledge about these basic units of life will go on so that our understanding and treatment of abnormal tissues will continually improve. □

R.F. Jarvis and D. Rossington are at Coulter Electronics Ltd, Northwell Drive, Luton, Bedfordshire LU3 3RH, UK.

Cells in the laboratory

A selection of equipment—some to be seen at the Atlanta meeting of the American Society for Cell Biology.

- Using the direct immunofluorescence staining method, Dako's conjugated rabbit antibody against human IgG (F202) demonstrates the presence of immunoglobulin deposits in the basement membrane zone at the dermal epidermal junction. Positive staining for IgG in certain skin biopsy sites can be a useful tool for distinguishing systemic (SLC) from discoid (DLE) lupus patients. Other helpful applications for this conjugate include the indication of skin disorders such as dermatitis herpetiformis and bullous pemphigoid.

Reader Service No. 100.

- Bioglass reusable microcarrier beads, fabricated from a plastic latex base with a thin layer of glass on the outside are ideal for cell attachment and for easy harvesting. They can be made in a range of specific gravities and sizes for cell culture and viral vaccine applications. Their near neutral buoyancy means easy suspension and slow stirring speeds. Bioglass microcarriers can be cleaned and sterilized like ordinary glass and reused up to 10 times with no degradation of cell growth capacity. European distributors and stockists for Bioglass microcarriers are European Business Associates of Luxembourg.

Reader Service No. 101.

Colourful tubes from Elkay.

- Elkay's expanded range of 1.5 ml microcentrifuge tubes now offers a choice of two materials and three colours. The range includes 19 different types of microcentrifuge tubes ranging in size from 250 µl to 1.9 ml. Precision moulded from polypropylene or polyethylene, an integral plug cap insures that the tube can be conveniently sealed to eliminate the risk of spillage. This feature also makes the microcentrifuge tube safer for transportation and storage as well as centrifugation. The tubes are available in blue, green and yellow for easy sample identification. These 1.5 ml microcentrifuge tubes can withstand the high centrifugal force generated by modern centrifuges.

Reader Service No. 102.

- A new synthetic microtubule inhibitor, R46846, has been synthesized by Janssen Research Laboratories. The *cis* isomer of tubazole-C, this reagent inhibits the rate and extent of rat brain tubulin polymeriza-

tion with an ID_{50} of 3×10^{-7} M—about three times as potent as nocodazole and 12 times as potent as colchicine. The novel antimicrotubule compound R17934 (see below) is also new from Janssen, and as it

R 17 934

(R 46 846)

(±)-*cis*
HCl

is chemically unrelated to the familiar microtubule-disintegrating alkaloids (colchicine, vinca and so on), it should provide a useful alternative in studies of microtubule involvement and function.

Reader Service No. 103.

- The Falcon Labware Division of Becton Dickinson has introduced newly designed tissue culture dishes called Easy Grip. With the Easy Grip feature, the lid and dish can be picked up and stacked easily and cleanly regardless of hand size. The design also keeps the contents undisturbed when removing the lid. Many researchers have claimed the design of conventional dishes makes the handling of the dish a difficult procedure and the contents are occasionally disturbed during the process. The first Falcon tissue culture dish to receive this design is the 35mm size.

Reader Service No. 104.

Getting to grips with the Falcon Easy Grip.

- Oncor Inc. has now developed reagents and protocols for *in situ* hybridization. Any 35 S- or 3 H-labelled probe may be used in this system for the detection of DNA or RNA target in cells or frozen tissue deposited on microscope slides. DNA or RNA targets are detected *in situ* under the microscope after autoradiography. Counter stains such as haematoxylin and eosin and Wrights stain are compatible with the system. All Oncor probes are available labelled with 3 H or 35 S for use with the *in situ* hybridization kit.

Reader Service No. 105.

These notes are based on information provided by the manufacturers. To obtain further details about these products use the reader service card bound inside the journal.

ADVERTISEMENTS

Fibroblast Growth Factor (FGF)

Improve your cell growth rate with **FGF**.

FGF is a potent growth factor that stimulates the proliferation of fibroblasts and epithelial cells. It is naturally produced by the placenta and is found in various tissues and fluids. FGF is a polypeptide chain of 44 amino acids with a molecular weight of 17,600. It is highly active and stable in solution.

FGF is used in a variety of applications, including the treatment of wounds, burns, and ulcers. It is also used in research to study the mechanisms of cell growth and differentiation.

The Accurate Chemical & Scientific Corporation range includes growth factors and ECM coating.

• Now available from Accurate Chemical of Westbury, New York, extracellular matrix (ECM) coating was developed expressly by IBT of Israel for simulating *in vivo* cell growth in an *in vitro* system. As a naturally produced substrate, ECM plays an active role in the control of cell proliferation and differentiation, and should provide greater study potential in cancer and haemostasis research, biopsy specimen growth, and other areas of clinical application. The culture ware is supplied pre-coated with ECM. Also new from Accurate is fibroblast growth factor, a stimulant of growth in tissue culture.

Reader Service No. 106.

Cytometry mechanized on the ACAS-470.

• The ACAS 470 workstation from Meridian Instruments functions as a "no-flow cytometer" that brings methods of automated clonal selection and fluorescence analysis to cell monolayers maintained in a tissue culture environment. This is accomplished through the integration of laser technology, epi-illumination microscopy and rapid, high resolution stage positioning — all under computer control. The intensity of the focused laser beam can be rapidly modulated to provide variable illumination for fluorescence excitation, photobleaching, cell surgery and cell killing. Fluorescent emissions are detected by a photomultiplier and digitized for storage. Results are presented on a colour graphic terminal. Coordinate locations of individual cells can be stored for automated time-based multiple analyses.

Reader Service No. 107.

• Beckman Instruments, Inc.'s Model L7-55 ultracentrifuge combines simple operation, reliable induction drive and built-in diagnostics with an attractive price. The induction-drive ultracentrifuge can run all Beckman high-performance fixed angle, vertical tube and swinging bucket rotors. Model L7 offers speed to 55,000 r.p.m. and forces to 408,000g for everyday applications. It operates at 2° to 20°C with thermistor temperature sensing.

Reader Service No. 108.

• Becton Dickinson has developed a new fluorescence activated cell sorter, the FACStar. This instrument incorporates the FACS cell sorter concept into a new user friendly design. The FACStar analyses cells or other biological particles, at the rate of ten thousand per second, using a laser beam. These cells are characterized on the basis of forward-angle light scatter, 90° light scatter and two-colour fluorescence. Individual cells of interest may then be physically sorted or separated. Operation of the FACStar is computer controlled. Single-key commands allow complicated analysis and sorting procedures to be performed without further operator intervention. The FACStar can also be operated manually so that performance can be quickly optimized without recourse to time-consuming software menus.

Reader Service No. 109.

• The new electron microscope from Philips, the CM 10, is aimed at life scientists requiring advanced instrument control techniques. Central to the CM 10 technology is the Microcontroller, a microprocessor-based microscope control system which links the operator console and the column hardware. It enables control elements to be assigned general functions rather than directly connected to specific lenses or deflection coils. Consequently, each function, such as image focusing, always occurs with the same function knob, regardless of microscope mode or the magnification applied. Operator communication with the Microcontroller is via an interactive screen. Microscope mode and observation conditions are labelled in the screen as are the functions of special CM 10 softkeys, through which both mode and conditions are determined.

• A new service from Molecular Biosystems provides custom-modified DNA. Modified oligonucleotides are available at 10–40 base units in length with a non-isotopic label. The modified SNAP oligonucleotides contain thymidine analogues with linker arms attached at C-5; such linker arms terminate in a primary amine or label of choice such as fluorescein, rhodamines or biotin. Amine-derivatized oligomers can be attached to solid supports for immobilization of hybrids. Labelled oligomers can be used for non-isotopic detection of complementary sequences.

• Auto-Count, from Artek Systems Corporation, is a new low-cost automatic counter for rapidly counting bacterial colonies. The AutoCount has an adjustable aperture which allows operators to isolate an object or group of objects for separate image counting. Simple adjustment of its size discriminator dial elimin-

Bacterial counting by Artek.

ates objects that are smaller than the determined size threshold. The AutoCount can also be manually adjusted to a proper sensitivity threshold. Every scanned object is flagged with an illuminated dot so the operator can see exactly which objects have been included in the count. Objects can be virtually any shape, clearly defined or hazy, dark or light. Artek is a subsidiary of Dynatech Corporation and the Auto-Count is available from Dynatech in the United Kingdom.

ADVERTISEMENTS

AFFINITY CHROMATOGRAPHY DISPOSABLE COLUMNS

For purification of mouse and human Ig, IgG, IgM, IgA from serum, ascites and tissue culture fluids.

AUTOMATED LOADER/ELUTER

For running affinity chromatography columns unsupervised overnight, weekends or all week.

RABBIT ANTISERA

A custom service for rabbit antisera against your own or our antigen. Whole serum, precipitated Ig, affinity purified antibody, fragments and conjugates.

ATCC
Catalogue of
Cell Lines & Hybridomas
5th edition, 1985

ATCC's catalogue now available from ATCC, 12301 Parklawn Drive, Rockville, MD.

• The fifth edition of the ATCC Catalogue of Cell Lines and Hybridomas has just been published, describing over 2,650 lines. The 305-page catalogue provides data on human, animal and plant cell lines; details on more than 200 hybridomas; a listing of cell lines involved in patenting; recommended media and growth conditions for many cell lines; and formulae for standard cell culture media and reagents. Lines are indexed by species, tissue cell type, tumour type, monoclonal antibody specificity, special applications (including virus studies) and originator's designation. Copies of the catalogue are available free of charge in the United States. Shipments outside the US will be charged \$6.50. ATCC is exhibiting its range at the meeting of the American Society for Cell Biology, Atlanta.

• The Coulter D10 Th is a semiautomatic diluter designed to provide dilution of platelet rich plasma (PRP), for use with the Coulter Thrombocounter. The D10 Th can be operated in any one of the three modes which all control the same dilution function. By pressing the black touchplate on the front of the instrument, by utilizing the optional pipettor, or by the convenient foot switch. All three operating modes enable the D10 Th to aspirate, and then precisely dilute 3.3 µl PRP sample in 10 ml of Isoton 11, all in eight seconds.

• Ricin A and B chains are now available from ICN Biochemicals. Whole ricin is a highly toxic protein of molecular weight 66,000 and is isolated from castor beans. The A chain is the enzymatically active subunit which interferes with protein synthesis, and the B chain binds to carbohydrate moieties and mediates entry into the cell. The A chain is virtually devoid of any toxic effects for whole cells as long as it is not attached to the B chain of ricin through sulphide bonding. The ricin A chain has been bound to monoclonal antibodies, hormones and numerous other cell surface ligands. Applications of conjugated ricin A include histological cell identification and removal of unwanted normal cells from suspensions.

Non-radioactive DNA label

The Orogenics DNA Chemiprobe kit was incorrectly described as a radioactive labelling system in *Nature* of 12 September. In fact the innovation is that Chemiprobe is a non-radioactive system for DNA labelling. For more details on Chemiprobe write in number 99 on the Reader Service Card.

• Bioscreen is a new automatic and compact analyser system from Labsystems. Using vertical photometry, the system measures microorganism growth. Practical applications are possible in many fields: food and beverages, cosmetics and toiletries, pharmaceuticals, water analysis, industrial effluents monitoring and basic biological and toxicological research. Bioscreen is fully automatic with a capacity for 200 simultaneous individual tests. Each testing cuvette is only 400 µl, therefore decreasing reagent consumption. And, the Bioscreen liquid dispensing system is easily autoclavable. Bioscreen consists of an analyser unit, a desk-top computer with customized software programs, a printer and disposables. The analysing unit itself contains a dispenser/diluter and an incubator connected to a photometer. The system sets on most any laboratory counter. During the test process, the computer reads information such as the initial cell population size, cell growth, growth speed and cell generations.

Polaron's latest microcomputer-controlled tissue processor.

• Polaron Equipment's new E9200 automatic tissue processor employs a bench-top microcomputer for system control, instead of the electromechanical card reader previously used. The use of the computer provides much more flexibility and is much easier to operate than the older system. The reagent delivery system incorporates eight separate reagent storage bottles, each with its own peristaltic pump. The E9200 handles all reagents from initial osmication to 100% resin embedding and is capable of processing up to 126 samples at one time.

• A new product data sheet from Schleicher & Schuell gives specifications for its Uniflo sterile, disposable laboratory syringe filters. Made with low protein-binding, pure cellulose acetate membranes, the 25-mm Uniflo filter offers high sample recovery, no extractables, and a process volume of up to 150 ml for materials as viscous as media with 10% bovine serum albumin. For each of the four available pore sizes (0.2, 0.45, 0.8, and 1.2 μm), a specifications chart gives flow rate, pressure rating, average hold-up volume, and application areas.

Reader Service No. 118.

• Nalge Company, a division of Sybron Corporation, has available a free wall chart to simplify the selection of the right filter for the job. This new four-colour chart includes complete selection and applications data for reusable filter holders and presterilized, disposable filter units, syringe filters and membranes. The chart also includes selection information for Nalgene 25-mm syringe filters, 47-mm membranes, and reusable holders.

• Bellco Biotechnology's new modular magnetic stirring system, the Sci/ERA quad drive, provides precision control of cell growth parameters for up to four remote stirring units from a single master controller. The one-to-nine position stirrer modules accept spinner flasks up to eight litres in size permitting convenient system expansion. Remote units are connected to the master controller via 10-foot heavy duty cables with locking plugs, allowing ample room to pass into or through incubators. System options include a sealed gel-electrolyte battery to protect cell cultures against power loss.

• The PSS-80 automatic peptide synthesis system from Applied Protein Technologies Inc. features a unique in-line reaction monitoring system, fifteen randomly accessible, refrigerated amino acid reservoirs and a negative pressure delivery system. APT's Custom Peptide Synthesis Service furnishes peptides promptly in quantities of 10 mg to 10 grams or more. All are sequenced to demonstrate their purity and integrity. APT's proprietary chemicals include PEP-TIES which are insoluble solid-supports for immobilizing peptides and proteins. For polypeptide isolation and purification, PEP-SEPS are amino acid specific immobilized reagents. PEP-SEPS facilitate the design of DNA probes by isolating specific peptides or peptides containing specific amino acids. APT products can be seen on Booth 326 at the Atlanta Cell Biology meeting.

Available from Techmation, the new VirTis chemostat.

• The VirTis Omni-Culture Chemostat bench-top fermentation system for continuous culture experimentation and aerobic/anaerobic studies is now available from Techmation. The system is designed to provide accurate, reproducible data, facilitating scale-up; it also regulates temperature, agitation, filtered air or gas flow and the transfer of medium. To maintain sterility throughout prolonged research studies, all components coming into contact with fermentation liquids are made of materials that are non-toxic, non-corrosive and repeatedly autoclavable.

Reader Service No. 122.

• A new vibration isolated bench from Photon Control of Cambridge is designed for electrophysiologists, neurophysiologists, cell biologists and molecular biologists using precision micromanipulators and probes of micrometre or sub-micrometre geometry. Users of the Model BT Series of biotechnology benches claim an ability to routinely investigate small cells (5 μm radii) with longer impalement times, and a substantial improvement in

signal to noise ratios. The BTT bench top is constructed from synthetic granite which consists of 96% solid granite aggregates bonded together, the remaining 4% is a special well damped matrix material.

Reader Service No. 123.

• The Skatron Microwash I and II 96-Well Automatic Microplate Washers have been designed for both enzyme immunoassay and radioimmunoassay applications; the versatile Microwash II has additional facilities which make it suitable for use with cell monolayers. The microplates are washed by selecting one of the three wash programs which permit either 3, 4 or 5 repetitions of the wash/aspirate cycle. The rinse program is used to prevent blockages caused by the build-up of crystalline deposits by flushing the wash liquid from the instrument at the end of the working day.

Reader Service No. 124.

• A new data sheet on the Kontes Micro Ultrasonic Cell Disrupter is now available. Designed to be capable of disrupting samples in a reproducible manner, the disrupter's LED output indicator provides a precise measure of the load imposed by a sample; previously documented responses can be confirmed to be re-occurring. Tip displacement amplitude is maintained by Kontes' monitor circuitry which assures stability by continuously correcting amplitude variations.

Reader Service No. 125.

• Optomax Inc. has introduced two new image analysis systems. System V is an automatic system utilizing dual microprocessors and high-speed measuring circuitry. Provision of circular and rectangular frames, variable in size and position, plus user-drawn frames, allows areas of interest within the image to be defined. In addition to a single detector, System V features a twin 'grey slice' detector and also a programmable 256 grey level auto detector. Vids V is a high resolution semi-automated system utilizing a graphics tablet and IBM PC or compatible computer. Input from the TV camera is viewed on the display monitor and features to be measured are 'drawn round' or 'dotted' using a hand-held cursor.

A compact Optomax image analyzer.

A seller's market for graduates

from Richard Pearson

Against the trend in other sectors, the demand for new graduates in scientific and technical subjects in Britain is strong.

EARLY last year the *Employment* column forecast that a revival in the job prospects for new qualifying graduates was imminent. In the event the upturn in recruitment has been faster and more widespread than anticipated, with employers from sectors as diverse as oil and chemicals, manufacturing, retailing and financial services all reporting growing numbers of vacancies. While the high fliers and information technology specialists have been in particular demand, graduates in the pure sciences and the applied sciences have also been beneficiaries. In 1984 the number gaining employment in industry and commerce was already 25 per cent higher than during the labour market doldrums of 1980–81 and is set to increase again in 1985. The one no-growth area is for jobs in higher education itself.

The International Labour Office (ILO) has recently highlighted the booming UK graduate labour market, and reports that it is not mirrored in most other countries. In the United States over half of new PhDs cannot find the type of employment for which they were trained. Unemployment among chemists and chemical engineers, for instance, was at its highest level for a decade in 1983. In West Germany, the number of jobless university graduates has quadrupled during the past four years to a total of over 115,000. Teachers, engineers, natural scientists, lawyers and economists were particularly hit. In France there were nearly 60,000 members of managerial and supervisory staff without jobs in early 1984, while in Switzerland, joblessness among young university degree holders has risen from 2 to 5 per cent in recent years — much faster than the general unemployment rate. Japan offered a mixed picture. Job offers for 1984 university graduates increased by 4.7 per cent as compared to 1983 thanks to a new phase of industrial innovation combined with an economic upturn; however,

openings for high school graduates were expected to decline by 12.9 per cent.

A common thread everywhere is that women graduates face more difficulties than men in finding and keeping a professional job, partly because a larger proportion of women take degrees in less "marketable" subjects, but also due to sex discrimination. In addition, the ILO report concludes, more and more professional workers are being forced to step down on the employment ladder and accept jobs for which they are overqualified, setting off a chain reaction which affects the entire labour market.

The final figures for the United Kingdom in 1984 show that of the 30,000 graduating in science subjects from the universities, nearly two-thirds went into employment, 15 per cent went onto further research and about 6 per cent went into some form of vocational training, the latter percentage having continued to fall sharply in recent years. Of particular note are the declining numbers entering teacher training; since 1980 the number has fallen by nearly one-third, and totalled just over 1,100 in 1984, of whom less than half were mathematicians or physicists. This means that the already serious shortages of mathematics and physics teachers is likely to get worse over the next decade. About one in eleven scientists were still seeking work six months after graduation. Of those scientists entering permanent employment, over half went into manufacturing industry, and about 14 per cent, a steadily declining fraction, entered the public sector. Less than four per cent got jobs in the education section while twice as many went into accountancy. In terms of actual jobs, the most common destinations were management services, and research and development and associated support activities. The pure scientists were more likely to go into further research or training, and also had higher

unemployment rates than the applied scientists, while more of the latter went directly into employment (Fig.1). Women were more likely to enter teaching than their male counterparts. The data for the polytechnics to be published shortly are expected to show broadly similar patterns.

On the salaries front the average for those starting jobs in autumn 1984 was about £7,000 per annum, with many companies in the growth sectors of oil and chemicals, electronics and information technology offering nearer £8,000 per annum. Salaries for 1985 are expected to be about £500 higher, with a few of the top payers in central London offering starting salaries in excess of £9,000 per annum as they seek to attract the "best" talent. Post-graduates with relevant degrees or experience relevant to the job being filled can command substantially higher salaries; most, however, receive salaries little higher than first degree graduates.

In the scramble to attract the "best" people, where, in the case of non-technical jobs employers often judge personal criteria before academic criteria, the traditional gentlemanly calm of the "milk round" is becoming outdated. In past years, virtually all the companies visiting colleges did so in the spring term, apart from the accountancy companies who were able to plead special circumstances and start their recruitment in the autumn term. Nowadays more companies start their recruitment campaigns before Christmas to try and catch the best students, and some are offering previously unheard of inducements such as "signing-on fees" if jobs are accepted quickly.

At the same time many students are becoming more confident of their job prospects and are concentrating on their examinations during their final year. They are delaying job search until after they have qualified, sometimes then taking a break of several months. In this way the graduate recruitment round, formerly concentrated into the spring term, is starting earlier, and extending later. If the anticipated growth in demand for graduates is matched by the expected fall in the numbers graduating then graduates who are well qualified, in both personal and academic terms, will be able to dictate not only the type of job they enter but also the time of year they seek work. □

Richard Pearson is at the Institute of Manpower Studies, Mantell Building, University of Sussex, Brighton BN1 9RF, UK.

How to tell success from failure

Next week's summit will have served its purpose if the participants merely agree that they should meet again. Some popular goals are unattainable, others deserve more attention than they will get.

Two people who have never previously laid eyes on each other will spend Tuesday and Wednesday of next week in each other's company under the most trying circumstances. Of late, President Ronald Reagan and Mr Mikhail Gorbachev have spent much of their energy in mutual public recrimination, which would be understandable against the background of the antagonism of the two governments they respectively lead, but which is hardly calculated to make for a cosy chat at Geneva. To make things worse, they have arranged to meet without knowing just what they will talk about if, as seems likely, they run out of things to say about their prime topic of conversation, arms control. Yet, as if to ensure that their social embarrassment will haunt them for years to come, the two leaders have encouraged people everywhere to expect great things from their encounter. *Pravda*, not to mention the *New York Times*, has for weeks had space for almost nothing else. This is one reason that the meeting is bound to seem a disappointment, a measure of the gap between people's expectations and reality.

Luckily, none of this implies that the meeting will be a waste of everybody's time. Those who expect wonders from Geneva should be content if the two participants agree only that they will meet again within the year. (Exactly a year from now would inconveniently coincide with the mid-term election season in the United States.) That alone would wonderfully repay the cost of all those airline tickets to Geneva. Less than that would be worrying for everybody. So an agreement to meet again is the least that must be looked for. What follows is a check-list of plusses and minuses by which departures of next week's meeting from that minimum should be judged.

Arms control

That arms control should be central to the agenda is natural, although the widespread belief that this is the sole touchstone of success is mistaken. Most of the recrimination of the past few weeks has centred on the US plan to build a defence against ballistic missiles, the Strategic Defense Initiative or SDI. The Soviet Union says that SDI is a provocation, the United States that a programme (not a plan) to make people everywhere safe from the threat of annihilation could not but be a boon, and that in any case the programme consists only of research; it could become a plan only a few presidential terms from now. Both sides are on solid ground, as in most confrontations born of conflicting interests. From the visit to Moscow earlier this month of Mr George Schulz, the US Secretary of State, it is clear that there will be little give or take on this issue at Geneva. The worst case will be that in which one or other of the participants digs in his heels on SDI, so as provoke a summit meeting as indistinguishable from a shouting match as that in Vienna in 1961, when the late Mr Nikita Khrushchev could not control his temper, read the still-new President John F. Kennedy a demeaning lesson and laid the ground for the Cuban missile crisis almost exactly a year later. The best hope is that next week's actors will perform a little more imaginatively.

A few ingredients could realistically be added to the minimum agreement to meet again within the year. In the field of arms control, there is no reason why the two sides should not agree in principle that there should be a treaty to prohibit either of them from destroying the other's Earth satellites. The Soviet Union

has been asking for such a treaty for the best part of a year, but the United States has replied by saying that it is at a disadvantage at this stage in the evolution of these esoteric weapons. Both perceptions may be correct, but the technology of anti-satellite (ASAT) weapons is at such a rudimentary stage that it would be wiser to live with an imbalance than to embark on the development. Thus an agreement in principle (the details would have to be worked out) to negotiate an ASAT treaty could take the edge off next week's disappointment, and would be worth having in itself.

ABM treaty

Another piece of frosting on next week's otherwise disappointing cake would be an agreement, again in principle, that the Anti-Ballistic Missile (ABM) Treaty of 1972, signed when the notion of *détente* seemed set in concrete, should now be reaffirmed and renegotiated. There are two problems. So much SDI talk has seemed to threaten the ABM treaty that reaffirmation is necessary, but the ambiguities that have allowed the US State Department and the Pentagon to disagree about the testing of SDI components need to be resolved. The treaty is ambiguous because its drafters did not know about SDI, but letting it lapse would be a setback. If SDI is indeed only a research programme, reaffirmation would cost nothing. Optimistic realists will be looking for one or other (or, preferably, both) of these refinements in next week's communique. The ground is not nearly well enough prepared for agreement to be reached next week, but a declaration of principle would allow the negotiators to get down to work. But all of this would be extra to the bare minimum agreement.

Familiar components of other arms control agendas will be absent from next week's agreement. Although the Soviet Union has been operating a unilateral moratorium on the testing of nuclear weapons (due to expire at the end of the month), there is no chance that the superpowers will agree next week to move decisively towards a comprehensive test-ban treaty. The United States is at present at a military disadvantage in being lumbered with the MX missile system, and will have a need to test warheads for whatever succeeds as the mainstay of its strategic force; giving up testing now would not be popular in Washington, but both sides are increasingly discomfited by the knowledge that even if there were a test-ban, France and China would stay outside. Difficulties about remote verification also persist, although less seriously than when the last round of serious negotiations began in 1977, but these might well be overcome by more liberal arrangements for *in situ* monitoring and on-site inspection. It would cost Mr Reagan and Mr Gorbachev nothing to agree that the draft treaty of November 1979 should be dusted off to see whether it will suit present circumstances.

But what of the issues central to the negotiations on strategic arms that have been under way at Geneva since the beginning of the year? The high expectations of next week's meeting stem from the enthusiasm that has been endangered for a substantial reduction of nuclear weapons. The two sides have indeed put forward proposals that outwardly differ very little from each other. The general idea is that strategic nuclear forces should be reduced roughly by a half. The Soviet proposal would selectively reduce present nuclear forces, the United States would limit

warheads instead. The obvious difficulty is that the viability of such comprehensive mutual restraint depends crucially on the details of an agreement, not its general outlines. The most that can be expected next week is that the two governments will acknowledge that the gap between them is not huge, and that they will then wish their negotiators at Geneva good luck. That, obviously, would be a plus. The corresponding minus is the danger that the Soviet Union will link the continuation of these potentially fruitful negotiations with a demand that SDI should be abandoned. That could spell a further deterioration of East-West relations, with possibly dreadful consequences. The question would be more rationally discussed when the draft of a treaty on strategic arms limitation exists, which is another argument for a second meeting.

What else?

The upshot is that there can be no firm agreement on arms control next week, but at best a series of agreements to agree. If there is to be a second meeting, the participants should therefore arrange that they will have other things to talk about. But what? Mr Gorbachev has been saying that arms control must be central to next week's talks, but that overlooks the truth that arms control is feasible only when political relationships are secure. President Reagan, trying to broaden next week's agenda, has been advocating (at the UN General Assembly) a partial list of the world's trouble-spots on which both Afghanistan and the Middle East are conspicuous, the second by its absence. In reality, such an agenda would cause more trouble than emollience. In the early 1970s, it proved possible to trade the promise of Soviet friendliness for that of US technology, particularly (as it turned out) the products of US farm technology now accumulating in the silos of the Middle West. No such easy accommodation is now possible. Nor is there much mileage in the almost ritual negotiation of improved scientific collaboration, the standby of politicians in need of something on which to strike agreement.

But why should not the United States and the Soviet Union negotiate some of the practical issues that divide them? The West's embargo on advanced technology, administered by COCOM, would actually be more coherent if the Soviet Union were given a chance to comment on the nonsenses that frequently arise. The endless troubles about spying in the past year could have been avoided if there were a general understanding about the line dividing the tolerable from the unacceptable. And the time will come when the two superpowers must talk about the political framework for the relationships between European states, East and West. It will be an uncovenanted plus next week if, having agreed to meet again, the two strangers agree to broaden future agendas in this way. □

Education in a mess

A new wave of anxiety about US science education may, this time, bring action.

SCIENCE and engineering education in the United States has frequently been held up elsewhere as a shining example to be followed. In Britain, for example, the many studies over the past two years focused on the shortage of scientific and technical skills have ritually applauded what has been done in the United States. But if US science education at the undergraduate level has the appearance of ruddy health, it is only skin deep. The system, if it can be called that, is in trouble. Science education is facing its biggest crisis since the panic that gripped the United States in the early 1960s, after the Soviet Union beat it into space with Sputnik.

It is true that in the United States undergraduate institutions seem to have adapted more quickly than those elsewhere to the booming demand for skills that have anything to do with computers, thanks largely to the recognition by many US science-based businesses of where their interests lie. (It also helps that the tax system is so weighted in favour of corporate giving that it would

be public relations suicide for a major corporation not to be seen to give away a few millions of dollars every year or so.) But there is more to life, and science, than desk-top computers. The problems are many, and are now being spelled out in painful detail to the National Science Board, the policymaking arm of the National Science Foundation. The board, to its credit, has established a committee (inevitably called a task force) to examine the problem and to see what the foundation should do about it. There is mounting and disturbing evidence that the quality of teaching in both public and private universities is declining. Faculty are ageing and are not being replaced at a sufficient rate, especially in engineering. Laboratory instrumentation is, despite corporate munificence, seriously out of date, particularly in institutions not famed as research establishments. And increasing teaching loads all too often force universities and colleges to rely on the teaching of undergraduates on new graduates, for many of whom English is not a first language.

Quantity is another and a daunting aspect of the problem. The proportion of young people in the United States going on to higher education in science and engineering is only a half of what it is in Japan, while there is mounting evidence that demand is being constrained both by the high cost of higher education and the continuing poverty of high-school education at all but the excellent institutions. Can the United States continue to be astonished at the imbalance of its trade with Japan?

Who is to blame for this mess? The National Science Foundation. No other federal agency can be expected to do the job. Since the late 1960s, the proportion of the foundation's budget devoted to science and engineering education has declined from something close to 30 per cent to rather less than 5 per cent. The foundation finally gave up pretending to take seriously its statutory obligation to education at the undergraduate level in 1981, when its paymasters in the Office of Management and Budget (backed by the new White House) snuffed out all but one of its activities in that area. The one remaining programme provides a niggardly \$5 million a year for laboratory equipment in non-research institutions.

The result of this neglect is that university teaching has come to seem a chore to faculty members at many institutions, not an activity vital to the function of an institution. (There are some honourable exceptions, chiefly among the private universities.) Research, by contrast, brings its own rewards, both intellectual and (mainly in the United States) financial. What could the National Science Foundation do to help? Plenty. It could make awards, symbolic and monetary, for the preparation and dissemination of teaching materials, preferably making full use of the still largely untapped potential of computers. It could arrange (and pay for) national meetings and teaching workshops where good teachers would describe their techniques. It could make special grants to graduate students who display real talent for teaching. It could even expand its teaching equipment programme to include the research universities. Most important, it could renew its commitment to the notion that in an advanced democracy some comprehension of science, even by those who will not later become professional scientists, is a necessity, not a luxury.

A credible programme for science and engineering education at the undergraduate level would provide what is at present lacking, a subset of university teachers whose primary commitment would be to excellence in education. The amount of money needed is not large by US standards: \$50 million would be a useful start, increasing to perhaps twice that amount over a few years. Fortunately, all the indications are, the colossal deficit notwithstanding, that Congress is sympathetic to the idea and is willing to give the science foundation a shove in the right direction: it has demanded a plan of action by next March. Happily, the task force's study will be completed before then, in January, and not before time. By any analysis, the strength of the United States rests on its scientific and technical workforce, as do all of its hopes for the future. There is no known alternative to diligent study and excellent teachers. Americans should not need to be told that. □

Indian technology

Quest for self-reliance runs into trouble

New Delhi

SCIENTIFIC research in India is being steered by Prime Minister Rajiv Gandhi in a new direction intended to take the country into the twenty-first century — fast. Gandhi has made it clear that his government will not tolerate “rubbish science” or inefficient industry, and that all research must be productive. Indian scientists have been told not to waste time in reinventing technologies that can be purchased, but to work on those that others are not willing to sell. His adviser Mr L. K. Jha has gone a step further in suggesting that industries should not hesitate to import not only technologies but, if necessary, whole factories as well.

The plans for the overhaul of research and development and liberalized import policy stem from Gandhi's conviction that Indian scientists have been pampered for too long without being accountable and that industries have enjoyed protection for years at the cost of efficiency. Scientists are now being asked to deliver and industries to compete and catch up. “India had been pushing hard on science while neglecting the technology aspect”, Gandhi told a recent press conference. “Our research and development must be such that it really ends up with a finished product.” Gandhi feels that India's 750 million people are entitled to a better deal from Indian technologists. Since they have failed, there should be no objection to importing foreign technology.

The Council of Scientific and Industrial Research (CSIR) is the first agency to be asked to streamline its research. Other ministries that preside over research establishments will follow. Gandhi has directed CSIR to concentrate on a few key areas or “technology missions . . . instead of frittering away energy on a whole gamut of fields.” Following Gandhi's directive, CSIR director general Dr S. Varadarajan has undertaken the massive exercise of revamping the research activities of the council's 40 or so institutes. Several CSIR projects that lack definite goals are to be axed and pilot plants that have failed to generate interest in industry may be scrapped. About half of CSIR research is related to developing “import substitutes”. Now that import is freely allowed, such projects will face closure. Basic research will be a casualty. As far as CSIR is concerned, the only basic research permitted is that relating to “frontier areas” such as biotechnology or microelectronics.

Not everybody in CSIR is happy about the shape of things to come. “Our Prime Minister wants us to leapfrog to the

twenty-first century”, says a senior scientist. “But we cannot get there without mastering twentieth century technology.” Although a month has passed since the review began, few technology “missions” have been identified. “We can easily close down unproductive projects”, says Varadarajan, “but it is not easy to replace them with new ones.” CSIR has about 20,000 scientists and technicians, and it is an open question how to relocate those whose projects are to be axed. In the past, Indian industry has been more or less forced to adopt CSIR technology. According to one CSIR director, requests for processes from his laboratory dropped from 77 in 1984 to four in 1985. It is feared that with industries free to import the best from abroad there will be no more takers for CSIR knowhow.

The liberalized policy on the import of technology has also come under attack from sections of the scientific community inside and outside CSIR, as is shown by recent controversies over the move to import silicon and fibre optics technology. Critics believe the import policy is a negation of self-reliance, the hallmark of Indian science during the days of Jawaharlal Nehru and Indira Gandhi. “Indian research and development has been castrated”, says Baldev Singh, former chief of the technology utilization division of CSIR. “The country's laboratories appear almost like condemned institutions”, says Mr P. S. Deodhar of the Electronics Trade and Technology Development Corporation. There is a fear that industries based on indigenous technologies will be wiped out and that CSIR will face a slow death.

The fear is not unjustified. A cottage industry making silicon-carbide crucibles, and a factory that just started making “chlorosilane” using CSIR technology are facing closure as these products can now be freely imported. CSIR spent eight years developing SWAT-106, a chemical that improves oil flow through pipelines. But now four multinationals are planning to bring in their own technologies for a flow improver.

The *Hindustan Times* in a leading article said: “More and more public undertakings are hankering after foreign deals little bothering to find out whether appropriate indigenous knowhow exists. What is the idea of having big scientific establishments if their talents cannot be utilized locally?”

In the electronics sector, the clamour for foreign collaboration is at its peak. According to Deodhar, the import policy is luring businessmen “whose motive is commercial rather than technical”. Consumer electronics items with international

brand names are being marketed by Indian companies that have sprung up overnight. Some 29 giant computer companies from abroad are planning to enter the market, virtually sealing the fate of the state-owned Electronics Corporation of India Limited.

According to Prem Shanker Jha, a noted economist, the present import policy has spawned literally hundreds of “screwdriver units” in the electronics and automobile industries, “the two potentially biggest customers of capital goods industries”. There are three foreign collaborations for passenger cars, 10 for commercial vehicles and 14 for scooters and motor cycles. The government-owned Maruti car factory has rejected an Indian consortium's offer to set up an engine production line in favour of a Japanese company. Britain is setting up a plant near Bombay that will make 12,000 electric vehicles a year, preempting the electric vehicle project of the public sector Bharat Heavy Electricals Limited (BHEL), which is itself purchasing anticorrosion technology from a US company, ignoring processes developed by a CSIR institute.

“From one extreme of self-reliance, the pendulum has swung to the other”, says Baldev Singh, “and many of the current imports in the name of high-tech are really irrelevant to taking India into the twenty-first century.” Meanwhile, the number of foreign collaborations shot up from 440 in 1984 to 752 in the first six months of 1985 and foreign exchange reserves dipped from £4,800 million in April to £480 million by the end of July.

The peculiar situation in Indian science today is that heads of scientific agencies who privately worry about the technology import policy publicly remain silent or defend it. Many agree that the 1982 technology policy statement (TPS), which warned against indiscriminate import, has now been more or less torn to pieces. But Professor M. G. K. Menon, planning commission member and architect of TPS, will not comment on the new policy. And Rajiv Gandhi's government still swears by TPS. “The government has not deviated from the concept of economic self-reliance and the liberalized policy of import will not throttle indigenous research or industry”, the Prime Minister recently told newsmen. But sceptics, including the president of the Indian National Science Academy Dr C. N. R. Rao, who strongly opposed import of silicon technology, still believe that liberalized imports will stifle indigenous research.

Professor Abdul Rahman, a former CSIR director and science policy specialist, has warned that modernization cannot be achieved with imports of technology. “This”, he said, “has been amply demonstrated in Latin America which is saddled with debt, and in Iran where the Shah's hurry to modernize with massive technology inputs led only to political crisis.”

Biotechnology

Diluted optimism at Osaka

Osaka

THE city of Osaka made its bid last week to establish itself as the Japanese "capital of biotechnology" with what was billed as "the first international conference on biotechnology". While that may be something of an exaggeration, the conference, thanks to generous support from the regional government, must have been about the first to hear experts from the Soviet Union describe their national biotechnology programmes alongside executives from many of the major biotechnology companies — Cetus, Calgene, Cytogen, Biogen, BioEurope and the like.

Within Japan, the Kansai region (which includes Osaka, Kyoto and Kobe) can fairly claim to have taken the lead in traditional rivalry with Kanto (the Tokyo-Yokohama megalopolis). Many of Japan's biotechnology companies have their research laboratories in the region, while Kyoto and Osaka University dominate basic research in molecular biology.

The state of international rivalry is harder to assess. Although Japan and the United States often regard themselves as the only players in the game, the European Communities representative was keen to scotch the view that Europe is not an active commercializer of new ideas. It was pointed out that most of the new (if still few) products of biotechnology were first produced in Europe: monoclonal pregnancy test kits (the Netherlands, 1980), biochemically produced human insulin (Denmark, 1982), recombinant amylase (Denmark, 1982) and recombinant α -interferon (Austria, 1985). Europe is also far ahead of the rest of the world in building new biotechnology research centres and providing integrated courses of study in the universities.

The UK outlook was more gloomy. Some praise was given to the establishment of new companies such as Celltech with "intellectual assets from the public sector and financial assets from the private". But there was a warning that lack of funds in Britain had pushed basic research to the brink of an irreversible decline; there may soon be nothing new to commercialize.

Japan's biotechnology industries are seen as building a better base for the long-term future. At present, commercial emphasis in the United States and Europe is on the production of new pharmaceuticals. That is where, in the relatively near future, completely new products, and new sources of profit, can be created. But it is in plant agriculture and food processing that the really huge returns on investment can be expected towards the end of the century. A very wide spread of companies in Japan has set up biotechnology research laboratories and knowledge of biotechnology is diffused through all kinds of in-

dustry. This diversity may pay dividends.

The Japanese tradition of focusing on production technology, rather than on an exotic end-product, is also at work in biotechnology. There is massive investment in exploiting biotechnology to improve existing processes — better bioreactors, enzymes, lipids and surfactants.

That biotechnology research is concentrated in large companies may also work in Japan's favour. A couple of years ago, Japan was bemoaning its lack of new venture capital while the United States was celebrating the host of innovative small companies into which the stock market was pouring money. But now there is a feeling that new venture businesses will not be big enough to capitalize properly

on their innovative achievements.

Not everyone was worried about international competition. The high level of cross-licensing agreements that has characterized the first phase of the growth of biotechnology, together with the diversity of uses to which biotechnology may be put, was seen by some as ruling out the kind of national rivalries found in electronics. But representatives from the South-East Asian countries were pessimistic. Dependent as many of them are on agricultural production, they stand to benefit most from biotechnology. But they have neither the facilities nor the manpower for large-scale research; recent developments, such as the successful patenting of new types of seeds, have them worried. The low attendance at lectures given by South-East Asian representatives must have helped confirm their fears.

Alun Anderson

Computerspeak

Hope for international standards

Washington

THE world is one year away from agreeing fundamental standards for controlling the communication of computers, according to the leader of the British delegation at a crucial set of meetings held during the past two weeks in North America. The negotiations involve more than half a dozen countries whose governments have been the most active since 1977 in attempting to arrive at a set of standards for inter-computer communications. The 300 or more delegates are here to discuss the latest development in Open Systems Interconnection (OSI).

The delegates are members of the sub-committees from the Geneva-based International Organisation for Standardisation and represent trade associations and government institutions. The main political impetus has come from the United States, Britain, Japan, West Germany, France, Canada and Scandinavia. The OSI meetings require the countries involved to move towards agreement on a comprehensive package of standards in seven distinct areas. These include the disciplines on how computers should be connected to telecommunications circuits, how those data can be stored and displayed, how one network can communicate with another to allow the "global addressing of computers", how errors in data in the network can be detected and corrected, how messages can be synchronized and their delivery controlled. The other standards enable types of data to be identified as they are transferred between computers over national boundaries and between different computer systems.

The sessions have been taking place in Toronto, Gaithersburg (Maryland), Syracuse (New York) and Durham (North Carolina).

Bryan Wood, leader of the UK delega-

tion, says "there is increasing support for a single standard independent of manufacturer". That indeed is the wish of the British government, which has refused to allow the UK telecommunications authority British Telecom to join with IBM to operate a data management network on the grounds that such a partnership would stifle competing systems and allow IBM's own standards to dominate. The IBM communications standard, recognized as a possible rival to OSI, is called System Network Architecture (SNA), and is still being developed in parallel with OSI.

The Europeans and Americans in particular hope that SNA will not hamper OSI development but that it will be used for intercommunications between IBM computers and that the OSI standard will be used for any other communication. The seven levels of the OSI standards, which are at various stages of ratification, are also meant to accommodate communications from any closed network to another.

Computers connected to each other within a factory or office complex would be examples of closed loops, called local area networks (LANs). Such networks will be able to be connected to each other using the OSI standards. They will be able to communicate with each other over an interconnecting network, possibly an international one, whatever the standard used at the local end. The Ethernet system originally devised by Rank Xerox and the recently announced IBM token ring, both forms of LAN, will be accommodated by the OSI standards, claim the delegates to the American conferences.

Bill Johnstone

Bill Johnstone, on sabbatical from his post as technology correspondent of The Times of London, will be writing on technology subjects for Nature during the next few weeks.

Eureka

Optimism in France . . .

"EXTREMELY satisfactory." That is how French research minister Hubert Curien described the results of the second ministerial conference on Eureka, the French-inspired initiative to develop new European high technology products, in Hannover last week.

The meeting decided on 10 projects, seven of which involve French participation. French officials were impressed that "the people who said no" to government finance of Eureka (which decoded means the British) are now saying "perhaps". Sir Geoffrey Howe, British Foreign Secretary, announced that British companies involved in Eureka projects could apply to the Department of Trade and Industry's £250 million annual "Support for Innovation Scheme", and said that he would not place an upper limit on the proportion of that fund that might be devoted to Eureka.

The French view, however, is in reality little different from the British. President François Mitterrand earlier this year announced that FF1,000 million would be devoted to Eureka in 1986, but it is now clear that none of this is new money, additional to the existing government research and development budget. According to Yves Sillard, the president of the French oceans and fisheries research council IFREMER and the man also responsible for the French Eureka projects, there will be no strictly new money in 1986. But more money could be provided later. As M. Hubert Curien, research minister, put it, there is now a line in the French research budget for Eureka, and this is politically defensible. M. Roland Dumas, foreign minister, stressed that the primary object of Eureka is to get new European technology on the market, thus emphasizing market pull rather than technology push—a point of view on Eureka adopted very early on by Britain.

According to Curien, the principal objective at Hannover was to make a list of projects, the first concrete plans, and that has now been achieved. With ten settled, fifteen more wait in the wings while detailed agreements are reached, and some 300 potential projects were on the table at Hannover, with many of them still in the running. "These are good days for Europe", Curien said.

These are, however, still honeymoon days for Eureka. No country or company has yet felt the pain of rejecting its own product in favour of one developed by outside companies under the Eureka label, which is what the logic of Eureka will ultimately demand. "There may be competing products even within Eureka", Curien added. "But we don't want the competition to lead to our losing the race with the United States or Japan."

According to Curien, Eureka will give

what would otherwise be merely a few bilateral or trilateral projects greater scale and greater speed than they would have outside Eureka. Eureka is accelerating what might have happened anyway, Curien said.

The controversial question of a secretariat for Eureka is to be decided, and the secretariat established, by 31 January next, but it should be small and "light", Curien said. Its location is not yet agreed, with countries divided roughly between those who support Brussels and a loose

connection with the European Commission, and those who do not. The French position is that the Commission's work and research should be treated as "complementary" to that of Eureka—which would argue, perhaps, for a Brussels base but not Commission domination of the Eureka secretariat.

Could multinationals be involved in Eureka projects? Yes, according to the French, if they had a base in Europe with independent power of decision. The role of countries beyond the 18 nations present at the Hannover meeting was not discussed, said Curien. Collaboration would not be ruled out but "Our object is clear. It is Europe, Europe." **Robert Walgate**

Eureka

But who is going to pay?

Hannover

In the eyes of the West German host delegation, the Eureka conference was a limited success. Both foreign minister Hans-Dietrich Genscher and research minister Heinz Riesenhuber praised the second Eureka conference as a "starting point for a progressive Europe".

Nothing of real substance was actually decided, it is admitted, but the 36 foreign and research ministers at least left with good intentions. For example, all were agreed that the third Eureka conference should take place next year in London. Following traditional EEC practice, discussion of the most urgent problems has been put off until then. The ministers also decided in principle to create a "small and flexible Eureka secretariat"—Britain and West Germany eventually agreeing to this French proposal. West German Chancellor Helmut Kohl and France's President François Mitterrand are backing Strasbourg as a location for the secretariat but there is also support for Brussels.

All participants agreed that Eureka projects should only serve civil purposes—in stark contrast to the original plans of the French, formulated after their refusal to take part in the US Strategic Defense Initiative (SDI). West Germany rejected all military aspects knowing that only civil purposes of the planned research would find support in this country, although like Britain and Belgium, Germany intends to participate in both Eureka and SDI.

The ten projects most favoured in the initial list include all three suggested by West Germany. The ten are: high-power lasers for material processing; a computer network for European scientific research; investigation of atmospheric pollution independent of national borders; amorphous silicon for production of electricity from solar energy; superfast vector calculators; robots for the textile industry; biotechnology; optoelectronic production systems; diagnosis of sexual diseases, in particular AIDS; European standards for home and school computers.

But there is still a cloud hanging over Eureka—there was no agreement about how to finance these ambitious projects. France made a gesture of offering to put FF 1,000 million toward Eureka projects: the West German government has not yet decided on the level of its support, preferring industrial companies to initiate and finance the projects.

Meanwhile criticism has come from some circles within German industry. If the industry is to finance the projects, why is it the politicians who meet to select them? The president of the German Trade and Industry Association, Wolf von Amerongen, went as far as saying that industry has absolutely no use for Eureka. The government disagrees. **Jurgen Neffe**

Refusniks appeal

LEONID Ozernoi, the Soviet Jewish astrophysicist who three years ago went on a protest fast coinciding with the eighteenth General Assembly of the International Astronomical Union (IAU) now seems to have lost faith in hunger strikes. In a message to the nineteenth General Assembly of IAU, which opens in New Delhi next week, Ozernoi says that his 1982 fast, and a similar, collective fast the following year with other refusniks seeking to emigrate to Israel had "disappeared without trace, like a black hole, in the depths of the Soviet emigration offices".

He adds that thanks to the support of friends in the Soviet Union and abroad, he has managed to stay out of prison or mental hospital and has not lost his job. But "nobody can be sure".

Ozernoi asks the participants at the IAU meeting to "raise [their] voices in protest against the retention of the refusnik scientists in the Soviet Union". To those who consider such appeals "inappropriate in the fight for peace", he says that silence will be interpreted as tacit support for Soviet attitudes towards the refusniks.

Vera Rich

Plant genes

Rifkin opens new campaign

Washington

JEREMY Rifkin, the campaigner against genetic engineering, has taken up a new cause: protection of plant germ plasm. In a suit filed in a federal court last week against the US Department of Agriculture (USDA), Rifkin, whose legal manoeuvres have held up field trials of genetically engineered microorganisms for two years, accuses USDA of "gross negligence" in looking after its collection of seed samples at Ft Collins, Colorado. The suit says the National Seed Storage Laboratory (NSSL) is so poorly managed and underfinanced that "thousands" of samples collected from all over the world are lost each year.

The Rifkin suit is the latest wrinkle in a highly politicized international dispute over the control of germ plasm. NSSL says it always makes available its samples (excluding narcotics) in response to a request from a qualified plant breeder, regardless of the request's country of origin. But Rifkin and his fellow plaintiffs, who include pressure groups from Malaysia, Spain and Canada, object to seed companies using the NSSL collection to develop usable breeds that may be highly profitable.

USDA drags feet

Washington

CONGRESSIONAL concern over the US Department of Agriculture (USDA)'s slow preparations to regulate biotechnology research is unlikely to be eased by a report published last week by the General Accounting Office (GAO). GAO found that in 1984 and 1985 together, the department will support biotechnology to the tune of \$40.5 million, including 87 projects that involve planned releases of genetically engineered organisms into the environment, most in the next five years. But GAO says that USDA was unable to provide information on the number, location and objectives of specific biotechnology research projects.

Denied official information, GAO conducted a questionnaire survey of institutions conducting USDA-supported research. The results of the researchers' own estimates of the risk of their planned environmental releases are, however, unlikely to surprise anyone. Asked whether their planned environmental releases would represent a reason for concern, 75 of the 87 contemplating such experiments checked the "no problem" box, nine the "very minor problem" box and three did not know. Asked what effort would be required to correct any problem that did arise, one solitary brave soul said a problem might be uncorrectable, noting, however, that this was the least likely outcome.

Tim Beardsley

The Rifkin version of this is that "industrialized nationals and transnational corporations attempt to seize control over the world's genetic resources in order to exert unchallenged power over the world's economy in the Genetic Age". The reason for the international involvement in a suit is that NSSL was for a time the principal repository of the seed collection maintained by the International Board of Plant Genetic Resources (IBPGR), an organization funded by the World Bank and the United Nations Food and Agriculture Organization (FAO) which has catalogued some 300,000 food crop varieties from around the world.

Rifkin says that NSSL, which is a back-up safety repository, has haphazard collection policies; that most food crops other than a few staples are not collected at all; that samples are inadequately documented; and that genetic variation in the samples is lost because seeds are planted out too infrequently and in unsuitable locations. Rifkin wants USDA's total budget for germ plasm increased from its current level of about \$12 million to \$40 million, the figure recommended in an internal USDA study and in a study by the seed company Pioneer Hybrid.

While rejecting some of Rifkin's specific charges, USDA officials say they accept that the suit has been brought in good faith and readily agree that the situation at NSSL is far from satisfactory. Dr Charles Murphy, of USDA's Agricultural Research Service, admits that lack of storage space is becoming "a serious problem"; NSSL has put in a bid for extra funds towards a new storage building to replace one that will soon be full. And Murphy agrees that NSSL's lack of knowledge about many of the samples it has received is its "biggest concern"; efforts are now being made to implement a new computerized database management system. But the figures Rifkin quotes for the proportion of unusable samples make "no sense", according to Murphy. Many samples have not yet received "plant identification" documentation simply because NSSL has not yet been able to ensure the stocks are viable.

Dr Lewis Bass, curator of NSSL, also says that germ plasm storage should be a "higher priority programme", as it "will have far more impact on mankind than anything in the space programme". He says NSSL could use more money but that "we do a good job with what we get". Nevertheless, he agrees that the process called "enhancement" — getting the useful properties into strong varieties that can be used by breeders — has barely started.

IBPGR officials decline to comment on the specific charges being levelled at NSSL; they say that it is only by maintaining a strictly apolitical stance that IBPGR

has been able in the past to deliver samples to any country in the world.

The international aspect of the row is likely to come to a head this week at an FAO meeting in Rome. There, IBPGR's cherished apolitical stance may be seriously threatened: radical Third World countries have demanded that IBPGR be given a statutory foundation and guidelines that would make patenting of seed varieties illegal. In order to avoid becoming politicized, IBPGR may have no choice but to duck out of FAO's sphere of operations and become an independent scientific body.

Tim Beardsley

Bioengineering

Plan for field tests of bacteria

Washington

THE first environmental releases of genetically engineered organisms are expected to be approved this week by separate US government agencies. The Environmental Protection Agency (EPA) will give the nod to Advanced Genetic Sciences of Oakland, California, to conduct a field test of a bacterium modified to protect from frost damage, while the National Institutes of Health (NIH) will formally approve a proposal by Agracetus of Wisconsin to field-test a modified tobacco plant as a model for studying plant viral disease resistance.

Advanced Genetic Sciences had voluntarily sought approval for its experiments from NIH, but withdrew the application after legal complications bogged down a similar proposal from Stephen Lindow of the University of California at Berkeley.

The environmental impact assessment for the Agracetus proposal was signed by NIH director James Wyngaarden in September; NIH officials have in the meantime been deciding how much of the assessment will be made publicly available. The decision is that the entire document will be released, with only the details of the test location deleted. But it is unlikely that NIH will become involved in future environmental impact assessments of agricultural field trials; under new rules recently adopted, NIH can leave regulation to another agency if this is considered appropriate, and EPA is likely to deal with most such proposals in future.

Advanced Genetic Sciences has produced a modified strain of *Pseudomonas syringae* which has had deleted from its genome the gene for an ice-nucleator protein which in natural *Pseudomonas* is expressed in the cell membrane and triggers the growth of ice crystals when the temperature drops below freezing. Experiments with *P. fluorescens* will follow. Tests will involve treating strawberry plants with the modified bacteria.

Tim Beardsley

Israel

Medicine confronts Jewish law

Rehovot

TENSION between Israeli medicine and Jewish law, as embodied in the Torah, is growing. The immediate difficulty is that the practice of autopsies and transplants is being inhibited by the provisions of Jewish religious law that the body of a dead person must be treated with the utmost respect, must be buried quickly and in its entirety, and must "not be exploited".

Dr Mordechai Halperin, the physician and ordained rabbi who heads the Schlesinger Institute for Medical-Legal Research at the Orthodox-oriented Sha'arei Zedek Hospital in Jerusalem, says that one consequence is that autopsies cannot be carried out unless there is a "reasonable and immediate" prospect of the saving of human life.

During the past few years, the numbers of autopsies carried out at Israeli hospitals have declined sharply, chiefly as a result of the Anatomy and Pathology Law of 1981, a result of pressure from the religious parties, which requires that an autopsy requires not only the authorization of three

physicians (as of old) but also the approval of the next of kin, and which allows the procedure to be blocked by almost any relative, even a distant cousin. At Halperin's own hospital, autopsies are now few and far between, perhaps fewer than a dozen a year. But he says that there is no necessary conflict between medicine and Jewish law, and that autopsies are no longer necessary for the training of medical students or even for confirming physicians' diagnoses. At Sha'arei Zedek, where full-scale autopsies require the consent of the hospital rabbi as well as that of a senior physician, post-mortem biopsies are quite common.

Elsewhere, the proportion of hospital deaths followed by post-mortem examinations has fallen to 10 per cent, but there are even fewer in Orthodox Jerusalem. Professor Haim Lichtig, a pathologist at the Haifa Technion medical school, says that students did not participate in a single autopsy last term, and that textbooks, films and the examination of preserved organs are a poor substitute for the "the real thing".

Pathologists such as Dr Nina Hurwitz of the Kaplan Hospital also argue that autopsies remain a valuable means of "quality control" in the practice of medicine, and that post-mortem biopsies or non-invasive diagnostic techniques such as CAT-scanning are inadequate alternatives; the discrepancy between clinical and pathological diagnosis has remained obdurately unchanged for 40 years, she says.

The availability of organs for transplantation is similarly constrained. Halperin says that Jewish law would treat as "murder" the removal of organs from a body whose heart was beating but whose EEG record was flat on the grounds that people had been known to recover from brain death. The removal of livers for transplantation would be permissible because artificial organs are not available, but kidney transplants are not always justifiable because kidney dialysis is possible. Halperin points out that life expectancy after kidney transplantation is not very different from that with dialysis.

The strict application of the law is not always accepted. One paediatrician who is religious considers autopsies necessary and has performed them himself. On kidney transplants, he suggests that one kidney should be removed from a dying person who may still be maintained by a respirator. Even some members of the Orthodox establishment appear to recognize that changes are required. Former Chief Rabbi Shlomo Goren, who also served as Chief Chaplain to the Israeli Army, is reported to have been furious that skin for transplanting to injured Israeli soldiers has had to be imported from overseas.

Nechemia Meyers

New RI director

PROFESSOR John M. Thomas, at present professor and head of the department of physical chemistry at the University of Cambridge, will become director, resident professor and director of the Davy Faraday Research Laboratory in the Royal Institution, London, on 1 October 1986, in succession to Sir George Porter, who has been nominated as president of the Royal Society.

French agriculture

More help for farm lobby

THE French government has taken further steps to strengthen the research base of its largest industry, agriculture. The ministers of agriculture, M. Henri Nallet, and of research, M. Hubert Curien, have announced a new programme to double government assistance to private research projects. This follows the earlier announcement that the agricultural research council (INRA) will be reorganizing its research programme so as to adapt more quickly to the opportunities in biotechnology (see *Nature* 24 October, p.660).

The stimulus for the new programme, which will take government support for private research to FF110 million a year, was apparently the discovery that agricultural and food companies spend only 0.25 per cent of their turnover on research.

Interestingly, the new assistance programme will focus on the downstream part of agriculture. The four principal themes are nutrition and toxicology, product quality, fermentation and food engineering. INSERM is also to pay more attention to the epidemiology of nutrition, while there is to be a global strategy of research on food and health.

The emphasis on food safety seems to derive in part from the recognition that if the European Communities manage to establish a central scheme for food and drug regulation, along the lines of the US Food and Drug Administration, French food exports could be jeopardized. But the government seems also to be anticipating a weakening of European price support for food and other produce and the more competitive market that would then come into being.

Robert Walgate

Academies go west

Washington

THE US National Academy of Sciences is going west. Together with the National Academy of Engineering, it has been given \$20 million by the Arnold and Mabel Beckman Foundation to establish a 50,000 square foot west-coast building complex consisting of an auditorium and meeting rooms at Irvine, California. The Irvine Company has donated a seven-acre site adjacent to the Irvine campus of the University of California, worth \$6 million.

Arnold Beckman, now 85, is the chairman and founder of Beckman Instruments Inc., of Fullerton, California, and has recently made multimillion-dollar donations to both of his former colleges, California Institute of Technology and the University of Illinois (see *Nature* 17 October, p.568). The gift to the national academies includes an endowment to maintain and staff the building, which will be known as the Arnold and Mabel Beckman Center.

Beckman pointed out that California now leads the nation in memberships of both national academies. During fiscal year 1985, the academies and related institutions held more than 2,000 meetings in their east-coast buildings in Washington DC and Woods Hole, Massachusetts, but only 70 meetings were held west of Colorado. The new building will be used to support the full range of the academies' activities; Beckman has, however, expressed a particular desire that it should be used for the study of social and ethical issues arising from developments in science and engineering.

Tim Beardsley

UNESCO

Soviet move too late?

THE United Kingdom, which has given notice to, withdraw from the United Nations Educational, Scientific and Cultural Organisation (UNESCO) by the end of the year, last week found an unusual ally in the Soviet Union, in the final days of UNESCO's Sofia conference. British delegates return home this week after a series of post-conference committee meetings and present ministers with recommendations for Britain's final decision.

UNESCO reaches its 40th birthday this month, but whether the battered organization will survive much longer has been called into question by the departure of the United States, along with 25 per cent of the organization's budget, at the end of last year. If Britain follows suit in December, as is likely, UNESCO will lose a further £5 million from its annual budget.

Timothy Raison, Minister for Overseas Development, spelled out Britain's worries at the beginning of the conference last month. The main concerns are that UNESCO is too top-heavy, bureaucratic, poorly managed and politicized, particularly in areas of disarmament policy (duplicating the work of other UN organizations) and government control of communications in the developing countries. Britain also considers that UNESCO should demand zero real growth in next year's budget and not increase contributions required of member states following US withdrawal. Specific proposals were presented to the conference as conditions for continued British membership.

Although several concessions were made to Britain in Sofia and the meeting was considered exceptionally harmonious by UNESCO standards, none of the major changes demanded by Britain were adopted. This always seemed unlikely; UNESCO's long-term strategy, the reason for convening the conference, was decided by its secretariat in Paris well before delegates arrived in Sofia — an example, in fact, of the centralized control that Britain is seeking to change.

A major stumbling block to the Western countries' demands for UNESCO's financial responsibility and an end to political patronage is acknowledged to be Amadou-Mahtar M'Bow, the director-general, a skilled manipulator, strongly supported by the developing countries. Hence last week's surprise development, in which the Soviet Union and its allies said that they would remove their support for M'Bow at the end of his term in 1987.

Whether this move will encourage the United States to open negotiations to rejoin UNESCO remains in doubt. And the events at Sofia may well not be enough to cause a last-minute change of heart amongst British ministers. **Maxine Clarke**

Satellite broadcasting

Direct service standards tested

Washington

A RIGOROUS and novel series of tests of the technical attributes of three different broadcasting systems has just been completed at the Lewis Research Centre in Cleveland, Ohio, under the supervision of the National Aeronautics and Space Administration (NASA) by the US interests in satellite television. The tests will be crucial in assisting the United States to adopt soon a technical standard for its satellites.

The tests were conducted by communications specialists and untrained observers under the auspices of the Direct Broadcasting by Satellite Association (DBSA, which represents most of the parties involved in the new industry). DBSA will present a summary of its findings and recommendations by the end of the year to the Federal Communications Commission (FCC), which in turn will give its ruling on technical standards to the four operators who now have approval for DBS satellite construction. The ruling will be made next spring at the earliest.

The Lewis tests were comprehensive. They began in the middle of September and were concluded two weeks ago. The three systems under test were examined in four principal areas — video (picture), audio, teletext (information display) and scrambling (coding signal). Experts and untrained observers gave subjective views on the quality of television pictures resulting from each system.

The systems tested were two forms of NTSC, the method now used in the United States in terrestrial broadcasting, and a version of MAC (multiplex analogue component), the system favoured, in a different form, by the United Kingdom. The results will play a significant part in determining the technical composi-

tion of the US DBS satellites due for launch in late 1988 or early 1989.

Several companies have expressed an interest in operating DBS television services in the United States since FCC invited applications for slots in the geosynchronous orbit. In June 1983 a sectional meeting of the World Administrative Radio Conference (WARC), the body internationally responsible for assigning broadcasting frequencies and satellite positions, allocated eight satellite slots to the United States.

There are at present four approved DBS systems — Satellite Television (a subsidiary of Comsat), United States Satellite Broadcasting, Dominion Video Satellite and Hughes Communications Galaxy. A further six applications for DBS services are being considered. If all are approved, the technical system adopted by the DBS operators for transmission must be able to prevent satellites from interfering with one another. Some will be using the same frequencies, but will have been separated in different slots, while others will be clustered in the same orbit but operating on different frequencies, as each slot can carry 32 channels.

All four approved operators plan multichannel systems of six to 10 channels. One aspect of the tests is to find out the degree to which each signal format is susceptible to particular interference.

The scrambling tests are also of vital importance as the DBS services are likely to be supported by subscription and may need to be protected from piracy. The Lewis tests checked whether signals could be received and viewed by pirates despite the protecting code and whether there was any deterioration in the signal quality received by the legitimate viewer because of the code's presence.

Bill Johnstone

Brenner to quit MRC post

BRITAIN'S top job in molecular biology will become vacant in 1987, when Dr Sydney Brenner plans to step down as director of the Medical Research Council's Laboratory of Molecular Biology at Cambridge. Brenner said last week that he plans to leave the laboratory at the age of 60, so as to be able to spend more time on his own research. He hopes to find himself a base elsewhere in Cambridge, and a small research group with which to pursue his present interests.

Brenner has been director of the MRC's best-known laboratory since 1979. An exile from South Africa by origin, Brenner joined the laboratory in 1957, when it was merely a barely tolerated collection of huts in a courtyard of the Cavendish Laboratory. During these early years, he worked with Francis Crick on the series of experiments that demonstrated that the genetic

code is a triplet code, and contributed substantially to the then rapidly deepening understanding of messenger RNA. More recently, Brenner has succeeded in opening up the study of the nematode *Caenorhabditis elegans*.

Brenner's spell as director of the Cambridge laboratory has been clouded by the consequences of a serious road accident in 1979, when a leg suffered a compound fracture. His colleagues marvel that his energy has been so little impaired.

The consequences of the vacancy at Cambridge will be considered by MRC at its meeting later in the month. The secretary, Sir James Gowans, said last week that all concerned are aware of the importance of the appointment, and that Brenner's successor will be sought on the international market. □

Climatic change with nuclear war

SIR—In August 1984, I pointed out in *Nature*¹ that the article by Turco and others² on nuclear winter did not arrive at a firm scientific conclusion, and is subject to numerous doubts. Fourteen months later, one of the authors, Carl Sagan³, moderated his statement, which had been reiterated in publications as diverse as *Parade*⁴ and *Foreign Affairs*⁵, that nuclear winter is a robust conclusion. His acknowledgement that the question must be further investigated is welcome. Unfortunately, the current article³ contains ambiguous and inaccurate statements.

As an example, Sagan³ quotes from the recent analysis by the International Council of Scientific Unions⁶. He fails to mention the conclusions of this study: that no nuclear winter is to be expected in the Southern Hemisphere, that considerable temperature declines could occur only in the northern latitudes in the summer and

the mid-continental areas. In mid-summer the effect will not be worse than those in fall or early winter. By contrast, the original TTAPS report, which Sagan calls a "valid first-order assessment", predicted a minimum hemispheric average temperature of -23°C .

To escape the danger of nuclear winter, Sagan suggested the reduction of stockpiles, which unfortunately requires faith in the reliability of Soviet compliance. Sagan has published in *Foreign Affairs*⁵

Fig. 2 The history of the relative numbers of US nuclear warheads. There has been a clear reduction in the total numbers. The scale is relative, with 1972 = 1.00.

data on the past and future numbers of nuclear weapons in the various stockpiles (Fig. 1). By contrast, the US government published⁷ relative figures on the time dependence of the American stockpile in regard to number of explosives and in regard to megatons (Figs 2, 3). It will be noted that the former have declined in the past two decades by 30 per cent, the latter by 75 per cent. This latter value is particularly significant in predicting worldwide effects. All of this was independent of disarmament negotiations.

To diminish the likelihood of the catastrophic impact of warfare, one should give most serious consideration to defensive measures. These may not only deter war but, in the horrible case of actual hostilities, the effect of nuclear war would be substantially reduced.

A basis of Sagan's claims is the work published by Alvarez and colleagues^{8,9} which adduces the presence of an iridium layer deposited 65 million years ago as evidence that an asteroid several miles in diameter hit the Earth. The subsequent dust excluded sunlight and led to the extinction of the saurians and many other species. On 11 October 1985, an additional paper was published¹⁰ where deposition of a terrestrial carbon layer was found to coincide with the iridium layer. The authors offer the plausible explanation that approximately 10^{30} erg was set free by a collision with an asteroid. This killed much of the vegetation, set forest fires and

gave rise to soot, the darkening of the sky and to the consequent biological catastrophe.

The survival of approximately half the living genera witnesses the toughness of life on Earth. A reasonable estimate of both the energy released and the smoke

Fig. 3 The reduction in the total yield of US nuclear weapons over the years. Relative scale, 1972 = 1.00.

emitted following the impact of an asteroid surpasses the total energy and smoke released in a nuclear war by a factor of 1,000. In this scenario the massive amount of smoke may well have overcome the effects of atmospheric moisture.

By contrast, in a nuclear war, as was pointed out¹, the mass of smoke is 10^{-4} times the mass of H_2O in the atmosphere at the corresponding latitudes. Thus an "asteroid" winter seems plausible but hardly a nuclear winter.

Both Sagan and I are rightly worried and are rightly considering the damage a nuclear war may produce. We differ in many respects, but most particularly in my concern about the direct and the intended effects of nuclear war, including the local effects of prompt radiation, while Sagan has concentrated on side effects. These side effects are obviously dwarfed by an event for which there is geological evidence.

CORRESPONDENCE

Origin of AIDS

SIR—In their recent review article in *Nature* (3 October, p.395), Wong-Staal and Gallo proposed that the HTLV-I virus originated in Africa and was brought to other endemic areas by commercial and slave trading dating back to the sixteenth century.

If this is true, I fail to see how the HTLV-I virus could have reached Alaska and Northern Scandinavia where it has been detected, and southern Japan where it is endemic. Japan was virtually cut off economically and politically from the rest of the world until the latter part of the eighteenth century. There was hardly any commercial trade between Japan and Africa before the twentieth century.

It is also important to emphasize that the presence of the HTLV-I virus in the vast expanse of continental Asia cannot be ruled out due to lack of epidemiological studies in the area.

Recent studies by the same authors now show that retroviruses highly similar to the human acquired immune deficiency syndrome (AIDS) HTLV-III virus occur not only in African green monkeys and macaques but also in some flocks of European sheep¹. These animals can all show AIDS-like symptoms with advanced infection. Hence the possibility of humans acquiring AIDS worldwide from animal sources cannot be overlooked. Indeed, such a possible origin of human AIDS has recently been proposed by Lewin².

Biotechnology aids

SIR—In your report (*Nature* 6 June, p.448) on plans for the computing facilities at the European Molecular Biology Laboratory (EMBL), only passing reference was made to the "Biosequences" workshop held at Grottaferrata (near Rome) on 24–25 May.

EMBL's plans were one contribution in a lively and wide-ranging debate on criteria and guidelines for the selection, by the European Economic Community (EEC), of projects contributing to the development of user services and research infrastructure for biotechnology in Europe. The workshop, sponsored by EEC, the Italian National Research Council and the University of Bari and organized by the latter, was timely in relation to EEC's current funding programmes for bio-informatics and for the development of the market in high quality information services. It also offered interesting comparisons and contrast between the various national activities of the

United States, the United Kingdom, France, Japan, Italy and Ireland.

Of interest was the emphasis by both structural researchers (A. Lesk of MRC, Cambridge) and molecular evolutionists (C. Saccone of Bari, R. Grantham of Lyons) on the need for a comprehensive approach, integrating all the diverse sequence, structural and biological data available in constructing and refining models and hypotheses (Compare with Lesk, A. "Coordination of sequence data", *Nature* 314, 318; 1985). The paper by B. Keil (Pasteur Institute) on the use of the proteolysis data bank to define the fixation sites of proteolytic enzymes illustrated the power of organized data.

These comprehensive and necessarily multidisciplinary approaches and the cost and difficulty of developing sophisticated and efficient software (for example C. Rawlings of ICRF on artificial intelligence approaches to structure prediction) and hardware (for example A. Coulson of Edinburgh on the application of distributed array processors to sequence comparison), lead to emphasis on better communication, networking and resource sharing between European centres. Training, users' clubs, electronic mail, software portability and on-line access were typical of the topics commended for support, complementing the centres and activities funded from national or EMBL resources. The workshop proceedings will shortly be available from the Research Directorate of the Commission of the European Communities (200 rue de la Loi, B-1049 Brussels).

Creationism unloved

SIR—In his letter (*Nature* 316, 184; 1985) C.K. Pallaghy, a senior lecturer in the school of biological sciences, La Trobe University, attributes the paucity of overt support for creationism by bona fide academics in reputable scientific departments to hostility to creationists by the hierarchy of their institutions and by their colleagues, and to fear of loss of respect and prestige generally. This attitude to creationists is hardly surprising in view of the methods they and their organizations adopt in promoting their fundamentalist religious views under the guise of "creation science".

Not content that our taxes are being used, through school grants, to support their fundamentalist Christian schools, they lobby vigorously for "creation science"

to be taught in the state schools and have already scored some success in Queensland. The creationists' acute aversion to evolutionism is such that they claim the *Genesis* creation stories to be the literal truth, despite their marked resemblance to Babylonian myths and to the mixtures of guesswork, poetic fantasy and folklore compiled by other races to account for the origin of man. So it is that Pallaghy, replying to a critic, had a letter last year in the Melbourne Age containing the passage, "first, does he realize that Noah's ark was immense (450×75×45 feet)? Its tonnage would have supported 4,000 fully grown African elephant bulls. There would have been plenty of room for all had God put young animals on board."

Everyone will agree with the creationists' right to believe whatever they like, but not with their wish to impose such beliefs on the young and vulnerable, in contradiction to the findings of the past several hundred years of intensely painstaking research — a priceless cultural heritage.

PhD theses

SIR—I wholeheartedly agree with Beverly Halstead (*Nature* 29 August, p.760) concerning the relatively trivial return of a British PhD thesis volume from the comparatively substantial cost (invested?) for the purpose of its production.

The advocated prerequisite for the PhD award of publication of scientific articles arising from the thesis material is, in fact, similar to the system operated by many universities and colleges in both Scandinavia and the United States. Indeed, some overseas establishments demand only that the material be published in a journal without requiring a formal bound volume. No doubt some would object to the adoption of such systems in this country but at least the various funding bodies would be able to assess the value of their investment more readily as well as providing additional incentives to the PhD candidate.

Incidentally, I was enlightened by Beverly Halstead's mention of costs for technical assistance during the period of postgraduate research. This clearly does not apply in every case since neither myself nor the postgraduate students in this and other departments were offered the benefit of technical assistance. We were simply informed that the PhD was supposed to be "an individual effort".

Multiple sclerosis and viruses

Evidence that human T-cell lymphotropic viruses are associated with multiple sclerosis may lead to identification of viruses that cause the disease — or to an addition to the list of failed candidates.

It is not every day that the Faroe Islands are mentioned in the scientific literature, but no contemporary review on the causes of multiple sclerosis is complete without a mention of them. While the disease was unknown in the Faroes before 1940, a mini-epidemic was recorded in the years after British troops were garrisoned there in 1940. There seems little doubt that an infectious agent was involved; it is now conventional to suppose that multiple sclerosis can be initiated by viral infection in genetically susceptible individuals. But which virus or viruses are the culprits?

Frustration has marked the hunt. By some counts, twelve separate viruses have at one time or another been implicated as initiators of multiple sclerosis. But in no case has the case been made to stick. So the first evidence of the frequent exposure of multiple sclerosis patients to a new virus type is bound to excite an equal mixture of interest and scepticism. Publication of the data, moreover, is bound to quicken the pace of the further research that will show whether the new type of virus is genuinely an initiator of multiple sclerosis, or whether it will join its dozen or so predecessors on a list of suspects. It is in this spirit that we publish, on page 154, the tantalizing but inconclusive evidence from Hilary Koprowski, Robert Gallo and their colleagues of an association between multiple sclerosis and the human T-cell lymphotropic viruses (HTLVs).

This provisional group of viruses comprises three members. HTLV-I was the first to be discovered, in 1980, and is the cause of adult T-cell leukaemia discovered in Japan. HTLV-II is a variant of HTLV-I; and HTLV-III (also known as lymphadenopathy-associated virus, LAV) is the cause of acquired immune deficiency syndrome (AIDS). Although HTLV-III lives up to this name in some ways, notably a propensity to infect human T lymphocytes, its nucleic acid sequence is not related to that of HTLV-I or HTLV-II. Another view, now strengthening, is that HTLV-III is more related to the lentiviruses than to the other HTLVs. Evidence comes from both structural comparisons and the fact that the HTLV-III can be found in brain tissues of certain AIDS patients (Shaw, G.M. *et al. Science* **227**, 117; 1985). Lentiviruses are animal viruses that cause progressive demyelinating diseases of the brain and spinal cord. Indeed, the disease caused in sheep by visna virus, the most studied of the lentiviruses, is often

said to be the best naturally occurring model for multiple sclerosis.

Inevitably, therefore, attention has been turned to the possibility that HTLV-III or a related virus is the cause of multiple sclerosis. Ironically, the evidence of Koprowski *et al.* is if anything more suggestive of an association between multiple sclerosis and HTLV-I or HTLV-II than with HTLV-III. Indeed there is no uniform response among the patients studied to tests for any of the three HTLV types; the authors say this conceivably indicates the presence of one or more entirely new HTLV-like viruses, possibly including a virus that combines some of the features of all three known HTLVs.

Leaving aside the identity of the viruses responsible for the signals detected in the tests, what and how strong are the signals, and to what extent can they be interpreted as evidence that the viruses in any way cause the disease? The signals are of two distinct types: the presence in the blood and cerebrospinal fluid of antibodies that cross-react with HTLV proteins, and the presence in cells cultured from cerebrospinal fluid of HTLV RNA. The former indicates that the viruses have been present, the latter that they are still present and active.

There are three problems in interpreting the antibody data. First, although it is clearly shown that the concentration of antibodies that cross-react with some HTLV proteins is greater in most serum and cerebrospinal fluid samples from multiple sclerosis patients than in various controls, such antibodies are not invariably present. Second, no consistent picture emerges as to which HTLV the antibodies are most closely related, although HTLV-I is much more frequently and usually more strongly implicated than HTLV-III. Third, and most important, it is already known that elevated concentrations of antibodies to measles and Epstein-Barr virus are frequently found in the cerebrospinal fluid of multiple sclerosis patients, throwing doubt on the significance of raised antibodies to other viruses.

For the data that indicate the presence of RNA that is related to HTLV RNA in cultured cerebrospinal fluid cells, at least there is no consistency of HTLV type. In the 4 out of 8 cases where RNA has been detected, it is related, though not very closely, to RNA of HTLV-I but not HTLV-III. When present, the RNA is detected in less than one cell in ten thousand,

which may at first seem too low to be of significance, but this rate is similar to the frequency of HTLV-III RNA in T cells of AIDS patients. Moreover, it is a general observation in chronic virus infections, including visna and measles, that only 0.1 to 1.0 per cent of cells in any tissue contain viral genetic information. Much more of a problem is that the controls are so far limited to two healthy subjects, neither of whom had HTLV-related RNA in the cells of their cerebrospinal fluid.

When Ashley Haase and his colleagues first reported measles virus RNA in several multiple sclerosis brains (*Science* **212**, 672; 1981), the data, together with those on elevated antibodies to measles virus in multiple sclerosis, made the measles virus a strong candidate as the initiator of the disease. But further investigations revealed that measles virus RNA can be detected almost as frequently in the brains of patients with other neurological and non-neurological diseases as in those with multiple sclerosis, weakening the case for the involvement of measles virus in multiple sclerosis, though not excluding it.

Clearly, more data, and particularly more controls, will be needed before the case for an HTLV-type virus as the initiator of multiple sclerosis can be realistically assessed: the National Multiple Sclerosis Society in New York has already organized several laboratories to begin participating in studies of the putative association with HTLV. There will also be intense efforts to try and isolate the virus or viruses that are the source of the HTLV-I-like RNA. Until that can be achieved, there can be little progress in understanding the variability of the HTLV-related antibodies in multiple sclerosis.

Even if a virus can be proved to be implicated in multiple sclerosis, it is likely to be merely the initiator of a chain of immunological events leading to demyelination of nerve fibres rather than a direct cause. It seems probable that the initial viral infection somehow triggers an autoimmune reaction against components of the myelin sheath of nerves. "The baroque complexities of contemporary immunology in its application to multiple sclerosis", as Byron Waksman puts it in summarizing current research on page 104, will require considerable unravelling before it is clear how the disease progresses from the triggering event.

Peter Newmark

Astronomy

When is a star a superstar?

from C. Martin Gaskell

How massive and luminous can a star be? The traditional upper limit to the mass of a stable main-sequence star is about 60 times that of the Sun, but superstars with masses thousands of times greater than this have been seriously considered for the power sources in quasars (or at least as possible progenitors of the supermassive black holes currently favoured as these power sources). The object R136a in the Large Magellanic Cloud has been claimed to be such a superstar. The latest observations¹, however, show that it is not a single object but a small compact cluster of bright stars, some of which nonetheless have a luminosity that exceeds that of the brightest known star in our Galaxy.

The dominant feature of the Large Magellanic Cloud — an irregular companion galaxy to our own Milky Way — is a gigantic region of star formation, visible to the naked eye, and known as 30 Doradus (the name comes from the 1712 star catalogue of John Flamsteed, the first astronomer royal). This nebula — often called the Tarantula — is the biggest region of star formation in our local group of galaxies. It is over 3,000 light years across and contains half a million solar masses of gas. In its centre are some extremely bright stars, dominant among which is HD38268. More commonly known as R136 (it was number 136 in a list of stars published by the Radcliffe observatory² in 1960), it is putting out enough ultraviolet radiation to ionize almost the entire Tarantula nebula.

What is R136? Studies at the beginning of the century showed it to have the spectrum of a very hot O star. In 1973, N. R. Walborn suggested that it was not one star but a small compact cluster of very luminous stars³. He argued that compact systems of a handful of bright stars within a light year or so were often found in the very centres of giant star-forming regions. The four stars known to amateur astronomers as the Trapezium, in the Orion nebula, are the nearest example. Walborn argued that if a system like the Trapezium were transported to the distance of the Large Magellanic Cloud, it would resemble a single star on photographs. Further work showed that R136 does have several components⁴ but two groups suggested that the brightest component (R136a) was a single massive superstar with a mass of 2,000–4,000 solar masses^{4,5}. Such a star would be very interesting as it would far exceed the conventional upper limit to the masses of normal stars. This limit, first derived by A. S. Eddington⁶, and named after him, occurs because the intensity of radiation becomes so great that radiation pressure exceeds gravity. R136a is in fact

losing mass at an enormous rate: Cassinelli, Mathis and Savage estimate it loses the equivalent of the entire mass of the Sun in 3,000 years⁵.

Better spatial resolution was needed to see if R136a is indeed a single superstar. The resolution of photographs taken by telescopes from the Earth's surface is set by turbulence in the atmosphere, and the very best photographs of R136a, taken in Chile, have a resolution of 0.7 arcseconds⁷. It was C. E. Worley, of the US Naval Observatory, who realized that R136a had already been resolved by visual micrometer measurements made 60 years ago⁸ but overlooked by modern spectroscopists. Worley, himself, made further visual observations in 1983 and published the results in a one page paper¹⁰ (perhaps the last time anyone will publish a visual micrometer observation of a double star in the *Astrophysical Journal Letters*). Worley's observations confirmed that R136a is actually two stars separated by 0.49 arcseconds with one (R136a₁) being twice as bright as the other (R136a₂). R136a₁, if a single star, would still be a very impressive object of perhaps 750 solar masses⁷. But is it a single star?

The issue has finally been settled by G. Weigelt and G. Baier using the technique of holographic speckle interferometry¹.

From 8,000 short-exposure pictures of R136, taken with the Danish 1.5 m telescope at the European Southern Observatory, they were able to reconstruct the true image of R136a because of the presence of the point sources R136b and R136c in the same field (holographic reference stars). Their conclusion is that R136a is actually a double star with a 0.10 arcsecond separation, and that there are at least 8 stars within a circle 1 arcsecond in diameter. Weigelt and Baier have therefore shown that R136 is indeed a complex of stars, much like the Trapezium in Orion, as Walborn had suggested.

Although nobody now believes 30 Doradus contains a 2,000 solar mass superstar, R136a remains highly interesting. Its three brightest components are each probably of more than a hundred solar masses, brighter than any star in our Galaxy. Many questions about the birth, life and death of such stars remain. □

Embryology

Interacting systems in amphibia

from Hugh Woodland and Elizabeth Jones

AMPHIBIAN embryos have long been a favourite experimental material for embryologists because their large size and independent development makes them particularly amenable to techniques like micro-injection and grafting. They are therefore particularly suitable for finding out how the variety of cells in the very early embryo differentiate. This kind of information is virtually non-existent for *Drosophila*, another developmental system much in favour at the moment. *Drosophila* work relies mainly on mutants and those available affect higher orders of pattern, rather than the basic events of cyto-differentiation. Thus, although the power of genetics cannot be applied to the amphibians, they still have a very important place in embryological research. Moreover, new life has very recently been injected into the study of amphibian embryology by the introduction of cloned DNA and antibody reagents which distinguish particular types of differentiation.

Until now, it has been necessary to rely

on purely morphological criteria for identifying tissues in amphibian embryos and, in many kinds of experiment, tissues may be very abnormal and their identification hard to justify, especially to those without extensive histological experience. Sometimes, as where cell division is blocked with agents that disrupt the cytoskeleton, the correct morphology of the tissue could not possibly appear. Cloned DNA molecules or antibodies (mostly prepared from *Xenopus* embryos) are being introduced to circumvent these problems. The DNA gives very accurate quantitative information but, since nobody has yet developed a viable method of *in situ* hybridization for early stages of amphibian development, spatial information is limited. The reverse is true of antibodies, which may readily be used for the immunohistological staining of sections.

How are the main tissues of the embryo generated? At the time of nervous system formation, all vertebrates have the structure shown in Fig. 1c. The considerable

tissue diversity is generally believed to originate from heterogeneity in the egg's cytoplasm, which is subsequently partitioned into different cells during cell division (cleavage). The small number of initial cell types thus formed are thought to interact with each other to generate further complexity. The original example of such an interaction, the 'induction' of the nervous system, was discovered by Spemann and Mangold over 50 years ago. Induction is the process in which the pathway of development of tissue A is changed by interaction with tissue B while that of B is unaffected. In the case of the nervous system, ectoderm is the responding tissue; in isolation it forms only epidermis, but placed with dorsal mesoderm (the future notochord and segmental voluntary muscle blocks) it forms nervous system (Fig. 1*g-i*). This invites the question of what causes the mesoderm to develop, and whence comes its dorsal-ventral polarity. This problem, which has received considerable attention lately, is especially interesting because the mesoderm is responsible for so much of the internal complexity of the body.

It was originally thought that the mesoderm arises from a special type of cytoplasm in the zygote, but there is no unequivocal evidence that the very early embryo contains more than two cell types, the ectoderm and the endoderm. The former develops from the pigmented half of the egg, the latter from the non-pigmented yolk half. In the 1960s, the field was revolutionized by Ōgi¹ in Japan and Nieuwkoop² in Holland. Nieuwkoop, who has not received the recognition appropriate to the importance of the work, concluded that the mesoderm is mainly or wholly formed by an induction in which the yolk endoderm induces its formation from ectoderm (Fig. 1*a*). This was shown by experiments in which animal and vegetal cells, neither of which form mesoderm in isolation, were removed from an embryo and grafted together (Fig. 1*d, e*). The result was the generation of mesodermal tissue (Fig. 1*f*), from which it can be concluded that a variety of mesodermal tissues may be induced from ectoderm that would normally form epidermis and nervous system. This basic result was soon supported by Nakamura's group in Japan³.

Very recently, cell-specific markers have provided a sophisticated confirmation of this process. John Gurdon, Tim Mohun and their colleagues in Cambridge have used cloned actin genes and an antibody to pick up the muscle component of mesoderm formed during mesodermal induction⁴; in Jonathan Slack's lab in Mill Hill, London, antibodies which react with muscle, epidermis and notochord have been used for the same purpose⁵.

These experiments have also more accurately established the dynamics of mesoderm induction. For example, even

in those experimental situations in which tissues have to re-establish communication, induction can take as little as 1.5–2.5 hours⁶. Furthermore, responsiveness of the ectoderm to induction and the ability of the endoderm to induce is lost in the early gastrula. It is important to know these kinds of details for at least three reasons. First, losses of responsiveness happen to be the first detectable signs that cells have adopted a particular path of development. Second, knowing when responsiveness and inductiveness occur should help in identifying the molecules responsible. Third, charting loss and gain of these properties will help in understanding the organ-building processes of early development. During the extensive morphogenetic movements of gastrulation, cells completely change their

that the agent is naturally relevant to mesoderm formation, even in the chick. The same is true of putative neural inducers isolated from amphibians⁷. In both cases, the next step is possibly to purify the putative inducers and generate monoclonal antibodies against them. These could then be tested for their ability to block induction and used in a strategy to clone the genes.

Oddly enough, the precise time when natural mesodermal induction occurs is still unknown. It might seem simple to take embryos at different stages, remove the cells normally expected to form mesoderm, and to find the earliest stage at which they develop, into, say, muscle. Unfortunately, throughout the likely period of induction, it is not possible to recognize any of the cells concerned. Fate mapping indicates that the general region

Fig. 1 Diagrammatic transverse sections of amphibian embryos in normal development (*a-c*) and in grafting experiments (*d-i*). Blastula stage embryo (*a*) with precursor ectoderm and endoderm, which interact (arrows) to form mesoderm between them. *b*, After gastrulation dorsal mesoderm induces (arrow) overlying ectoderm to form nervous system. *c*, Neurula stage, the main body organs are mapped. If the animal cells and vegetal cells are removed (*d*) and combined (*e*), they interact to generate mesodermal tissues (*f*). If dorsal mesoderm is removed from one embryo (*g*) and placed ventrally in another (*h*), the latter develops two sets of axial structures (*i*).

neighbours. If cells maintained a fixed response to a certain set of stimuli, or if the stimuli were always present, abnormalities could result. New phases of mesodermal induction can, and almost certainly do, occur later, for example during formation of the tail⁶ and perhaps the muscular cells of the iris.

We need to know if there is any unity in these processes, but there is unlikely to be much advance on this front until the molecular basis of at least one type of mesoderm induction is established. Progress has been slow in this direction. Although usable assays exist, they indicate that embryos at the appropriate stage contain only minute amounts of the substances that cause mesodermal induction. However, agents that cause induction have been isolated from more abundant sources, such as late-stage chick embryos or guinea pig bone marrow. A few micrograms of the chick agent have recently been purified and 10 nanograms of this 13,000 M_r protein have been shown to be sufficient to induce a nervous system⁷, though it remains to be proved

which forms mesoderm also contains cells which normally form endoderm or ectoderm, and which are capable of interacting to generate mesoderm up till at least the gastrula stage. Thus it is not possible to prepare an appropriate tissue fragment that is demonstrably incapable of undergoing new induction, even if the normal interaction has already occurred.

This same problem bedevils attempts to show that part of the mesoderm might be produced by an area of egg cytoplasm containing localized mesodermal 'determinants'⁸. Although the overall region that forms mesoderm in isolation contains probable ectoderm and endoderm precursors¹⁰, improved cell-marking techniques show that most of the mesoderm comes from the pigmented half of the embryo¹¹, which forms only epidermis in isolation. This strongly supports induction as the natural mechanism of mesoderm formation, since the pigmented region must develop into mesoderm only through the proximity of the yolk half of the embryo.

The mesoderm itself is obviously non-

homogeneous; its dorsal side contains the notochord and somites, as well as the neural-inducing ability, while the blood islands are ventrally located (Fig. 1b, c). Nieuwkoop, himself, first clearly showed that this vital dorsal-ventral polarity is imposed by the endoderm², experiments which have been elegantly refined by Bob Gimlich and John Gerhart in Berkeley¹². In its turn, the dorso-ventral asymmetry in the endoderm arises from cytoplasmic movements in the egg, polarized by the entry of the sperm — as discovered in the 1930s but now explored in some depth by the Berkeley group¹². The result is that the dorsal endoderm is formed on the side opposite sperm entry.

The simplest explanation of subsequent events is that there are three kinds of cell interaction that bring about mesoderm induction. First, (though not necessarily temporally so) there is mesoderm induction, which alone produces solely ventral mesoderm. The ventral nature of this effect is shown by obliterating the polarizing effect of the sperm on an embryo, for example by UV irradiation, whereupon a radially symmetrical embryo develops; most of the mesoderm forms blood cells, and none of it forms notochord or somites¹³. Second, the dorsal endoderm somehow instructs the overlying future mesoderm itself, to become dorsal, that is notochord and somite. This can be shown by transplanting pairs of blastomeres at the 32-cell stage¹², or by a modification of the operation shown in Fig. 1d-f, in which endoderm from future dorsal and ventral sides was transplanted separately^{14,15}. The third kind of interaction occurs within the mesoderm itself. Dorsal mesoderm influences the rest, perhaps through generating a morphogen gradient, to produce the dorso-ventral pattern of structures outlined in Fig. 1c. This is

demonstrated by the famous Spemann and Mangold experiment in which the dorsal mesoderm is grafted into a ventral position (Fig. 1g, h); a second set of notochord, somites and nervous system is generated, and the result is a 'siamese-twin' embryo (Fig. 1i). The influence of the graft on its surroundings is shown by the fact that the secondary set contains host cells as well as those of the graft¹⁵.

Sorting out the detailed cell and molecular biology of these interactions, as well as the generation of the initial cell heterogeneity by cytoplasmic determinants, needs simple experiments (like the grafts shown in Fig. 1d-f) that can be adapted to provide routine assays for the molecules involved. Fortunately, the development of such assays will be greatly facilitated by the cell-specific markers currently being developed, not least because they will make it possible to bypass time consuming histology. □

Human disease

Mechanisms in multiple sclerosis

from Byron Waksman

THE splendor of the great stairs and ceilings of the Würzburg Residenz, created by Balthazar Neumann and Tiepolo, provided a fitting backdrop for a recent discussion* of the baroque complexities of contemporary immunology in its application to multiple sclerosis (MS), a crippling disease of young adults.

Susceptibility to MS seems to be under multigenic control, with links to *HLA-D* locus genes *DW2 (DR2)* on chromosome 6 (C. Jersild) and possibly to IgG allotype genes (*Gm-1, 17;21*) on chromosome 14 (J. Pandey *et al.*). A role for genes governing the T-cell receptor subunits and/or vasoactive amine sensitivity, suggested by

the results of animal studies (see below), remains conjectural, as is the significance of increased frequency of spontaneous and induced chromosomal translocation in MS cells (G.R. Sutherland).

The evidence that MS in susceptible individuals is initiated by viral infection, at least in some cases, is increasingly persuasive. For the epidemic in the Faeroe Islands that followed the arrival of British troops in 1940, it seems that approximately 2 years of exposure to the putative infectious agent was necessary and that the period from infection to onset of clinical disease was about 6 years (J. Kurtzke). Susceptibility was low before puberty. In informal discussion, it was mentioned that MS elsewhere is associated with infections

(measles, mumps, rubella, Epstein-Barr virus) caught significantly later in age than in HLA-matched controls (A. Compston, O. Andersen). In a well-studied cohort of patients, over 25 per cent of exacerbations were associated with such viral infections; from two weeks before to five weeks after infection, the exacerbation rate was increased more than threefold (W. Sibley).

Viruses such as measles, rubella, and varicella have been shown to sensitize T lymphocytes to myelin basic protein (MBP) in some subjects; this sensitization is very frequently associated with 'post-infectious' encephalomyelitis (R.T. Johnson). In a study of such encephalomyelitis associated with rubella, multiple T-cell clones obtained from cerebrospinal fluid showed equal reactivity with the virus and with MBP (P. Marquardt). Three independent computer searches have indicated the possible chemical basis for this cross-sensitization by demonstrating the presence of homologous peptide sequences in encephalitogenic regions of MBP and in antigens of measles, influenza, canine distemper, Epstein-Barr virus and several papova and adenoviruses (R. Fujinami, U. Jahnke *et al.*, G. Stoner).

A key point of current research is to determine the exact location where specifically-immune T Lymphocytes, circulating in the blood, first recognize myelin (or other) antigen, 'presented' in conjunction with major histocompatibility antigen (Ia). In agreement with the findings in animal studies, Ia has now been demonstrated on the endothelium of blood vessels within MS lesions and on activated astrocytes near the edges of lesions, as well as on the population of infiltrating macrophages (U. Traugott). MBP has also been demonstrated at these locations. Thus presentation sufficient to trigger T cells in the blood, or such T cells as enter the perivascular space, may occur at the luminal surface of the endothelium or the foot processes of the astrocytes. In older lesions, presentation may take place on the cell bodies of astrocytes, or other glia, and on the surface of macrophages.

The early MS lesions, triggered in the white matter of the central nervous system by these reacting T cells, show vascular injury with leakage of fluid, invasion of the tissue by a mixed population of lymphocytes and macrophages, and myelin destruction (C. Raine, H.L. Weiner). T lymphocytes, mostly of the T8⁺ class but with some T4⁺, predominate. Haematogenous macrophages play the principal role in myelin destruction at the advancing edge of the lesion (J.W. Prineas) by a mechanism that seems to involve receptor-mediated endocytosis. That the ligand for the receptor may be antibody is suggested by immunoglobulin 'capping' on many of the actively phagocytic macrophages. But extracellular lysis of myelin is also seen: oligodendrocytes at the edge of the lesion look healthy, while those in contact with lymphocytes or macrophages show mor-

*"Multiple Sclerosis — Current Experimental Work and Some Clinical Perspectives" Würzburg, 29–31 August, 1985.

phological evidence of cell damage.

T cells found in the cerebrospinal fluid may reflect events in the central nervous system. Both T8⁺ and T4⁺ types are present and many carry markers characteristic of long-term cell lines (Weiner). There is one report of cells specific for MBP in very acute cases of MS (R. Lisak and B. Zweiman), but most studies of specificity suggest that the T cells are polyclonal and that many are MHC-autoreactive (A. Salmi, G. Birnbaum). The cerebrospinal fluid also contains raised levels of γ -interferon, even during clinical remission (R. Hirsch). The B cells and plasma cells of the lesions and the cerebrospinal fluid show a polyclonality that is comparable to that of the T cells and affects all the major immunoglobulin classes (K.P. Johnson, H. Link). The much debated 'disappearance' of T8⁺ cells from the peripheral blood early in acute attacks (J. Antel and B.G.W. Arnason) has been attributed either to their actual migration into the target tissue (Weiner) or to modulation of their phenotypic markers by, for example, prostaglandins released from activated monocytes in the circulation (P. Dore-Duffy, J. Merrill). A striking new finding is the absence, in most patients, of cytotoxic T-cell precursors specific for measles virus (H. McFarland). There is no comparable deficiency for influenza virus.

For many of these crucial new findings, the study of animal models with conditions that resemble MS has led the way. Experimental allergic, or autoimmune, encephalomyelitis (EAE), induced by immunization with MBP or proteolipid protein, may take a chronic relapsing or progressive form, particularly if immunization is at the time of weaning (equivalent to puberty) (Raine, D. McFarlin, F. Lublin, T. Tabira). Certain temperature-sensitive mutants of the JHM virus produce a subacute or chronic inflammatory demyelinating disease in rats that is associated with sensitization against MBP; lymphocytes from these animals produce typical EAE in normal recipients (H. Wege, R. Watanabe). Theiler's murine encephalitis virus (TMEV) produces similar disease in SJL mice and certain other strains (H. Lipton); although there is an immune response against myelin, the continuing reaction may be directed at persistent viral antigen (Lipton, P.L. Lampert).

The use of recombinant inbred mouse strains has shown there to be multigenic control of susceptibility to the MS-like disease, as well as to its intensity and character, in both EAE and TMEV models. For EAE, both high-responder and low-responder strains have been found (Lublin). The high responders, most frequently associated with *H-2^s*, readily develop chronic relapsing or progressive disease. Earlier studies in acute EAE had mapped the responsible *H-2* gene to *I-A* (R. Fritz). Genes controlling vascular sensitivity to vasoactive amines are also important (S. Linthicum). For the TMEV sys-

Acute phase

Systemic virus infection (measles, varicella, influenza)

Primary (cross-reactive) immunization to MBP

Circulating T lymphocytes specific for MBP

Systemic interferon (α , β , γ) response

Activation of vascular endothelium (and astrocytic foot process?) by viral particles and/or by γ -interferon

Expression of Ia in vascular endothelium body-wide and in CNS

Acute phase events in CNS vessels

Expression of Ia and presentation of MBP

Dual recognition by MBP-specific T cells

Activation of T cells leading to nonspecific secondary inflammation

Leakage of fluid producing oedema

Invasion of tissue by monocytes (macrophages), T cells and B cells

CNS tissue damage by oedema and invading cells

Demyelination by activated macrophages

Damage enhanced by local antibody forma-

tion, complement from circulation, free oxygen radicals (?)

Arrest of conduction, due to fluid pressure, loss of myelin, and perhaps T-cell lymphokines and free MBP

Chronic phase

Activated T cells produce IL-2 and γ -interferon locally

Activation of astrocytes by γ -interferon

Expression of Ia, release of IL-1 and prostaglandins by astrocytes invading macrophages

Proliferation, synthesis of GFAP, gliosis

Activation of Ia-reactive T cells in response to Ia, IL-1 and IL-2 in lesions

Persistent foci of Ia-reactive T cells

Continuing nonspecific secondary inflammation

Systemic virus infection-reactivation of process

Astrocyte activation by systemic γ -interferon

Renewed activity of local Ia-reactive cells

Enlargement of existing lesions

New lesion formation, as in acute phase

MBP, myelin basic protein or other myelin antigens; Ia, major histocompatibility complex antigen (Class II); IL-1 and IL-2, interleukins-1 and 2; GFAP, glial fibrillary acidic protein; CNS, central nervous system.

tem, an important genetic control, related to the intensity of the T-cell mediated response against viral antigen, maps to *H-2D*; another seems to be related to the gene encoding the β -chain of the T-cell receptor.

Lines or clones of T cells specific for MBP produce acute or chronic EAE when activated (with mitogen or specific antigen) *in vitro* and transferred to normal syngeneic recipients (I.R. Cohen, H. Wekerle). The delay of 72–96 hours before the first inflammatory cells appear in the central nervous system (R. Meyermann) can be accounted for by the time required for the transferred cells to produce heparanase, which permits them to penetrate the vessel wall and enter the tissue (Cohen), and to produce γ -interferon, which activates vascular endothelial cells and astrocytes. The delay includes time for both cell types to synthesize and express Ia, which can be demonstrated on macrophages infiltrating lesions (W. Fierz, Sobel).

An important new finding is that purified endothelium from brain vessels can be stimulated *in vitro* by activated T-cell supernatants or purified γ -interferon to express Ia and present antigens such as MBP to specifically sensitized T-cells (McFarlin). Similar data for purified astrocytes have been reported (B. Fontana). The importance of presenting myelin antigen in association with Ia is clearly established in experiments with cell lines transferred from, or to, either of two rat strains and their F1 hybrid (C. Lington). JHM virus particles, however, are capable of directly activating astrocytes without mediation by γ -interferon (P. Massa). Manoeuvres which stimulate systemic γ -interferon and/or reduce suppressor T-cell activity trigger relapse, even in normally resistant animals, such as Lewis

rats that have recovered from acute EAE. An important confirmatory finding is that MBP-specific suppressor cells are present in the spleens of sensitized rats during periods of remission but not during exacerbation (W. Lyman and C. Brosnan).

A hypothetical sequence of events in MS, which merges findings reported at the symposium with reports in the recent literature, is presented in the table. Several points of attack for potential therapies are suggested by the scheme. It would be worth testing the value of monoclonal antibodies directed at phenotypic markers or characteristic activation antigens of appropriate T-cell subsets; at the T-cell receptor or its subunits, particularly idiotypes related to specific myelin antigens; or at Ia (Weiner). Hybrid or toxin-linked antibodies may be advantageous. Other leads come from studies of EAE. Vaccination with MBP-specific lymphocytes, inactivated with X rays or mitomycin C, induces resistance (idiotypic tolerance?) to actively induced EAE (Wekerle); lymphocytes inactivated by hydrostatic pressure (which changes the physical state of membrane glycoprotein) are particularly effective, inducing a resistance that is transferable with T cells (Cohen); prolonged treatment with MBP plus galactocerebroside not only turns off chronic EAE but promotes remyelination, perhaps due to oligodendrocyte stimulation by antibody to galactocerebroside (Rodriguez).

All in all, participants at the meeting were imbued with a sense of optimism that both the complex scientific problems related to MS and the practical issues of its prevention might be nearing solutions. □

Cell metabolism

Organization in the cell soup

from Hans V. Westerhoff

METABOLITES moving directly from one enzyme to the next, enzymes sticking to each other and to membranes, intracellular water diffusing freely, energetics and kinetics not matching actual metabolism: in a recent workshop on *The Organization of Cell Metabolism*^{*}, these and related observations fell into a coherent picture. Rather than a thick, homogeneous soup consisting of metabolites and proteins at high concentration, the cell sap emerged as a bouillon with vermicelli. The vermicelli corresponds to a lattice of structural proteins to which cellular enzymes are adsorbed; metabolites move directly between the enzymes adsorbed next to each other, and where available, membranes can take over the role of the lattice.

As examples of the organization of metabolism through the dynamics of enzyme kinetics itself, glycolytic oscillations in yeast (B. Hess, Max Planck Institute, Dortmund) and oscillations in cyclic AMP concentration and movement in *Dictyostelium discoideum* (A. Goldbeter, Université Libre Bruxelles) were discussed. The models assumed the enzymes to be dissolved in a homogeneous solution of metabolites. However, the highlight of the workshop was the understanding of the spatio-temporal organization of metabolism arising from the breakdown of this very assumption. For instance, the *in vitro* desorption of NADH from α -glycerolphosphate dehydrogenase was reported to be greatly accelerated by excess lactate dehydrogenase, suggesting direct transfer to that enzyme. In general, direct transfer of NADH seems to occur between enzymes that bind it in the *syn* conformation and those that bind it in the *anti* conformation, which makes sense mechanistically (S. Bernhard, University of Oregon). In some cell types, most of the hexokinase is bound to a pore-forming structure in the mitochondrial outer membrane; glycerokinase added to a mitochondrial preparation does not effectively compete with the bound hexokinase for mitochondrial ATP (J. Wilson, Michigan State University).

These are extreme cases of 'metabolic channelling' — the transfer of metabolites from an enzyme molecule producing them to an enzyme molecule consuming them without equilibration with a 'pool' of the same metabolite. Such channelling can be either 'static' (where the two enzymes form a steady complex), or 'dynamic' (where metabolite transfer is contingent on the enzymes colliding).

In vitro, association of enzymes is often rather weak and dependent on low ionic strength (L. Kanarek, Vrije Universiteit

Brussel). But if the enzymes also bind to a support, the ensuing cooperative binding may suffice for physiological conditions. The inhibitory effect of oxaloacetate on the binding of citrate synthase to submitochondrial particles, suggests that association of enzymes may well be a point of metabolic control, which would explain why such association tends to be weak (P.A. Srere, Veterans Administration Medical Center, Dallas).

In view of this lability of enzyme supercomplexes, assay methods for channelling in intact systems have to be either delicate, such as the 'gentle' opening of cells that is necessary if cellular enzymes are subsequently to be shown to co-elute on chromatography columns (P.D.J. Weitzman, University of Bath), or based on functional properties implied by channelling. Several examples of the latter were presented. First, there is more rapid increase in specific activity of intracellular proteins than in that of intracellular amino acids upon extracellular addition of labelled amino acids (D.N. Wheatley, University of Aberdeen). Second, lactate is produced in toluene-permeabilized cells from glucose-6-phosphate but not any other added glycolytic intermediate (D.B. Kell, University College of Wales). Third, intermediary metabolites injected into frog oocytes fail to lead to the isotope dilution expected if metabolism were not channelled (T. Ureta, Universidad de Chile). Spatially inhomogeneous NAD(P)H fluorescence, after similar injections into mammalian cells, has been observed (E. Kohen, University of Miami). Another approach focused on the one-to-one relationship expected in static

channelling between enzymes producing a metabolite and enzymes consuming it, and on the implication that an inhibitor of the former enzymes would not affect the titre (with respect to the pathway flux) of an inhibitor of the latter. In membrane-linked free-energy transduction, this type of experiment provides an indication of channelling (D.B. Kell).

Nuclear magnetic resonance experiments have suggested that the inside of a cell resembles a thick but homogeneous soup. It is not obvious why channelling should occur in such a soup. Now, however, an alternative interpretation seems to prevail. The apparent seven-fold reduction in the self-diffusion coefficient of water is now thought to reflect the presence of barriers to (otherwise free) diffusion. Thus, shrinking of cells causes a reduction of translational, but not rotational, motion of a water-soluble electron-spin resonance probe (A.M. Mastro, Pennsylvania State University) and quasi-elastic neutron scattering suggests that, when measured over a few Angstroms, the diffusion coefficient of intracellular water is reduced only by a factor of three rather than seven (J. S. Clegg, University of Miami; C. Hazlewood, Baylor College of Medicine, Houston).

Against the background of structural information on the cytomatrix, there emerges a picture of an ultrafine structural lattice ramifying throughout the cytoplasm. Most of the intracellular protein is loosely attached to the lattice and water is free to move the short distances in between its threads. As was shown for artificially co-immobilized enzymes (A. Friboulet, Université de Compiègne), the proximity of the adsorbed enzymes will result in channelling. □

Plate tectonics

Palaeozoic longitude problem

from A. G. Smith

GREAT strides have been made in quantifying global geology for Mesozoic and Cenozoic time — the past 250 million years. This success has depended on magnetic surveys of the ocean floor and on measurements of the magnetic field preserved in rocks on the continents. But the situation is quite different for Palaeozoic time (245–570 Myr), because virtually all the Palaeozoic ocean floor has gone down subduction zones, to be recycled into the mantle, thus destroying half of the critical data needed to reposition one continent relative to another. But a recent paper by L.P. Zonenshain, M.I. Kuzmin and M.V. Kononov (*Earth planet. Sci. Lett.*

74, 103; 1985), of the P.P. Shirsov Institute of Oceanology in Moscow, presents some new Palaeozoic reconstructions which are considered by the authors to have brought a solution within sight.

By appealing to plate tectonic theory and using Euler's theorem — which states that the motion of a tectonic plate can be represented by rotation about an axis through the Earth's centre and a point on the surface — geologists can make precise reconstructions of the relative positions of the Mesozoic and Cenozoic continents from the oceanfloor data. By assuming that the Earth's magnetic field has always been a dipole whose axis lies parallel to

the axis of rotation, they can put these reconstructions into their former latitudes from the inclination and declination of the magnetic field preserved in continental rocks of the appropriate age. There is no difficulty at all in estimating the relative longitude separation of the major continents for the past 180 Myr or so, as the longitude inherent in palaeomagnetic measurements is resolved by the ocean-floor data.

When two continents are fixed with respect to each other, their relative positions can be found by superimposing their apparent polar wander (APW) paths, which in theory should be identical. Gondwanaland has been reconstructed by this method, but then it was independently known that Gondwanaland was a single continent during the time interval for which the APWs were compared. If the motion between the continents is small, then applying the method will give a reconstruction that will contain relatively small errors. The problem in using this method for an arbitrary period in the past is knowing how much of the difference between two similar APWs is due to errors of measurement and how much to relative continental motion.

By adopting a criterion of minimum motion between the continents in time, Mesozoic and Palaeozoic reconstructions have been made on the basis of palaeomagnetism alone, and are not dissimilar to those based on oceanfloor spreading (Irving, E. *Nature* **270**, 304; 1977). More recently, R.A. Gordon, A. Cox and S.O'Hare (*Tectonics* **3**, 499; 1984) argued that Euler poles can be inferred from long APWs of the continents, though this use of the palaeomagnetic data contains hidden assumptions that should be more closely examined.

An alternative method of making reconstructions is to use the hotspot reference frame as a means of repositioning the continents. Provided hotspot traces are available for all the continents, they can be placed in the same frame independently of any other data and the longitude problem can be solved. R.A. Livermore, F.J. Vine and I (*Geophys. J. R. astr. Soc.* **79**, 939; 1984) have tested this idea as applied to the past 90 Myr and have shown that the differences in latitude inferred from the palaeomagnetic reference frame and the hotspot reference frame are less than 7°, with the pole enclosed by, or within a degree or two of, the α -95 circles of confidence for that interval. For the previous 90 Myr the difference progressively increases to nearly 20°, possibly because the hotspot frame for the Jurassic and Cretaceous periods is not well known. In cases of incomplete data, hotspots could be used to orient one or more continents, the remainder being oriented using palaeomagnetic Euler poles. If there are more than enough data, these methods can be combined appropriately to find the best solution. This is the approach the

A reconstruction of the positions of the continents in Cambrian time (roughly 550 Myr ago). Modified from Zonenshain, L.P. *et al.* (*Earth planet. Sci. Lett.* **74**, 103; 1985).

Russian group have attempted to use.

The problem with using the hotspot frame for Palaeozoic reconstructions is that no Palaeozoic hotspot traces had previously been suggested. What Zonenshain and his co-workers now propose is that three examples of igneous activity within Eurasia represent continental hotspot traces for the time periods 400–365 Myr, 400–320 Myr and 280–130 Myr. Taken together with approximate Palaeozoic reconstructions from palaeomagnetic Euler poles, these traces would enable the relative motions of the Palaeozoic continents to be found in the hotspot frame. The most striking difference between previous reconstructions and theirs is in the Cambrian. The continents are not only much closer together but are also in a different order, with Siberia lying between western

Europe and North America (see the figure).

One of the major problems in this kind of work is the scarcity of reliable and well-distributed palaeomagnetic data. Granted that, one question is what is the significance of the palaeomagnetic Euler poles? In essence, the method assumes that any long APW consists of arcuate segments joined together by cusps (Gordon *et al. op.cit.*). The cusps are interpreted as representing important periods of plate reorganization, the arcuate segments as periods of steady motion. The existence of cusps, or at least of sharp changes in the trend of an APW, is well known and almost certainly reflects a discontinuity in the motion of the continent concerned, such as its separation from, or collision with, another continent. But what of the arcs between? Obviously, any arcuate path on a sphere can be described geometrically by a pole and an angle. What is the evidence that such poles refer sufficiently closely to the same reference frame, so that they are useful guides for reconstructions of past continents as opposed to reference frames that differ significantly from continent to continent?

A second obvious question is whether there are any hotspot traces on other Palaeozoic continents. If not, does the systematic age progression in the igneous activity in Eurasia have a different origin, such as one related to progressive rifting? Whatever the eventual answers to these questions, the paper by Zonenshain *et al.* will stimulate much further research and discussion. □

Palaeoanthropology

The earliest *Sivapithecus*?

from Eric Delson

THE search for a fossil ancestor (or even an extinct close relative) of the human lineage has met with mixed success over the past few decades. During the 1960s, the view that *Ramapithecus* was an ancestor of humans as contrasted with the great apes became dogma in anthropology¹, questioned by few workers and those usually on invalid grounds. Sharper attacks on this position characterized the 1970s, as details of molar enamel thickness, dental proportions and wear patterns revealed little difference between this taxon and *Sivapithecus*, its contemporary in 9–13 million year old rocks in India and Pakistan^{2,3}. Finds of more complete specimens attributable to *Sivapithecus* confirmed the similarity of these taxa and moreover permitted the inference that this expanded *Sivapithecus* group shared derived facial and dental features with *Pongo*, the living orangutan^{4,5}. This

left the fossil ancestry of human and African apes, joined phylogenetically by numerous generic and biomolecular studies⁶, open to question. Minority alternative views have arisen which suggest that *Sivapithecus* is ancestral (or at least closely related) either to all great apes and humans⁷ or to orangutans and humans alone⁸.

New evidence on the morphology and temporo-spatial distribution of *Sivapithecus* is therefore of great interest in this discussion. On page 173 of this issue, Leakey and Walker⁹ report and briefly describe new fossils from Buluk, Kenya, which they assign to an indeterminate species of *Sivapithecus*. This information is potentially exciting because the fossils are found in sediments that are more than 17 million years (Myr) old, as documented on page 175 by McDougall and Watkins¹⁰, far older than the earliest Eurasian fossils assigned to *Sivapithecus*. Based on this

age, Leakey and Walker now accept that *Sivapithecus* could well be the common ancestor of all later large apes, but realize that it tells little about the divergence of either the African lineage (Homininae: chimp, gorilla, human) or Asian (Ponginae: orangutan) lineage implied by molecular studies. But how accurate is their "unequivocal" identification and subsequent phyletic assessment, and what more (or less) can be inferred from these fossils?

Before these questions can be approached, it is useful to review the Buluk primates and other known occurrences of Miocene large apes. The fossil primate material from Buluk is rather scrappy, but four species are said to be present: three 'apes' of varying size and a more common species of Old World monkey. Although not cited by Leakey and Walker, the monkey has recently been described in detail by Meave Leakey¹¹, who assigned it to *Prohylobates*, a genus otherwise known only from slightly younger deposits in Egypt and Libya¹², rather than to *Victoriapithecus* of the Kenyan? Early to Middle Miocene (or about 17–15 Myr)^{13,14}. This apparent affinity with northern rather than eastern African taxa is mirrored in the remainder of the Buluk faunal list, which suggests either that the environment was more open than other Early Miocene sites nearby (perhaps akin to that of the Kenyan Middle Miocene sites Maboko and Fort Ternan) or that there was an influx of immigrant species.

Of the Buluk hominoid primates, a few specimens are referred to a small species, most to the new *Sivapithecus*, and an isolated tooth and dentulous mandible fragment to *Kenyapithecus wickeri*. The last taxon, intermediate in size, is best known from Fort Ternan but has also been reported from Maboko and nearby Majiwa¹⁵ and from Emuruiem (Nachola)¹⁶. There is still some controversy over the name and number of species of *Kenyapithecus* to be recognized but, despite previous synonymization with *Ramapithecus*, most authors now accept that *Kenyapithecus* is a distinct African mid-Miocene genus. While Pickford¹⁷ has grouped *Kenyapithecus* with the *Sivapithecus*–*Pongo* clade, Andrews¹⁷ places it on a separate lineage predating the Ponginae–Homininae divergence, because of its lack of derived *Pongo*-like features.

A number of other fossil 'populations' may also be relevant to understanding the Buluk specimens. In Asia, *Sivapithecus* is well documented in the Indo-Pakistan Siwaliks at about 12.5 Myr from remains with the distinctive facial characteristics seen in more complete younger specimens but, on dental evidence¹⁸, may extend back to over 14 Myr; recently, remains as young as 5.5 Myr have been assigned to this genus¹⁹. In Pakistan, the most complete fossils date to about 8 Myr. A large sample (probably representing a single species with high sexual dimorphism, contra Wu and Oxnard²⁰), of similar age from

China has also been placed in *Sivapithecus* and/or *Ramapithecus*²¹ but may require reassessment. The wide interorbital spacing and distinctive high-crowned incisors are not comparable to Siwalik *Sivapithecus*, although dental morphology is similar.

Sivapithecus has also been identified in Turkey and eastern Europe as old as 15 Myr, mainly on the basis of thick molar enamel, which Martin has shown to be a more complex character than previously thought²². The identification of *Sivapithecus* in Greece (see ref. 23) has been more widely accepted²⁴. De Bonis and Melentis²⁵ have now reported that the maxillary morphology of the Greek fossils, which they term *Ouranopithecus*, is more similar to that of hominines than *Sivapithecus* (see ref. 5). Kelley and Pilbeam²⁶ have suggested that the morphology thus revealed was derived and they have linked *Ouranopithecus* to hominine ancestry, but I prefer the de Bonis and Melentis interpretation that hominines share the ancestral morphology of this region, with the pongines like *Sivapithecus* being derived. Given that *Ouranopithecus* does share other derived features with *Sivapithecus*²⁴, it seems best to retain all the Eurasian thick-enamelled Miocene apes in a single clade.

In the light of this diverse assemblage of African and Eurasian Miocene larger hominoids, it is somewhat surprising that Leakey and Walker⁹ only compare the Buluk fossils to *Proconsul* and the Siwalik *Sivapithecus*. The novel faunal elements would suggest a wider search for comparative samples. Based upon the description and a brief examination of casts (courtesy of Walker), it seems to me that at least one alternative interpretation of the Buluk material is possible, if not more likely — that it represents a large *Kenyapithecus*. Pickford¹⁷ has presented new metrical data on *Kenyapithecus* which support the idea that the Buluk *Sivapithecus* is the male of a species whose female is identified there as *Kenyapithecus*. For example, his estimate of the length of a male upper canine of *Kenyapithecus* is slightly greater than that given for the Buluk male, while molar lengths are comparable to, or slightly smaller than, those estimated for Buluk from roots; Leakey and Walker⁹ do not give the direct measurements of the few relatively complete molars they have.

More to the point is the comparison of maxillofacial and mandibular morphology and enamel ultrastructure. The Buluk mandible is stated to be "remarkably similar" to an edentulous one from the Pakistani Siwaliks, but while this is so by comparison with *Proconsul*, there is little to differentiate among the Eurasian forms, all of which share superior and inferior transverse mandibular tori as well as a deep and thick corpus. The Buluk maxilla is not specifically compared with any Siwalik specimen, but the described morphology does read like that seen in several Asian *Sivapithecus* faces. It is not clear,

however, that the described pattern is unique to *Sivapithecus* or is as well developed in Buluk as in the Eurasian fossils. An enamel thickness of 1.5 mm is given for the cuspal region of one broken, but little worn, upper molar, somewhat less than the 2–2.5 mm recorded for Pakistani *Sivapithecus*²⁸. Martin²² has shown that ultrastructural detail (unknown in this case) as well as size normalization, is needed to make an accurate estimate, of the enamel pattern, but the Buluk fossils may present the "intermediate-thin" pattern, predicted by Martin but not yet observed. (Neither *Kenyapithecus* nor *Dryopithecus* has yet been analysed.)

The essence of Leakey and Walker's comparative analysis is that since the Buluk fossils are not *Proconsul*, they must be *Sivapithecus*. While the first part of this syllogism is unquestioned, their conclusion is by no means inescapable. The lack of even superficial comparisons with *Kenyapithecus*, with the Moroto maxilla (which has long been assigned to a large species of *Proconsul*²⁷, but may be of Middle Miocene age⁵ and thus rather younger than most of that taxon) or with *Dryopithecus* is surprising. It would seem, in fact, that an allocation to *Kenyapithecus* would be both more biologically parsimonious and reasonably supported by the morphological evidence. That *Kenyapithecus* is positioned close to the divergence of Ponginae and Homininae is thus reaffirmed, but the implications for the broader phylogeny of large hominoids in terms of palaeontology or molecular-clock calibrations are uncertain. □

PREPARE NON-RADIOACTIVE DNA OR RNA PROBES

with

PHOTOBIO TIN™

Forster et al. (1985), *Nucleic Acids Res.* 13: 745-761
Patent pending for preparation and use of Photobiotin and related compounds

DNA OR RNA PHOTOBIO TIN PROBES

- Simple to prepare by light-activated coupling
- Long storage life
- Sensitivity equivalent to ³²P
- Low cost: 1 mg Photobiotin labels 1 mg of DNA or RNA
- No radioactive hazards—ideal for teaching

- DETECT SINGLE COPY GENES ON SOUTHERN ANALYSES
- APPLICABLE FOR NORTHERN ANALYSES
- SENSITIVE DOT BLOT DETECTION

Photobiotin Acetate—Cat. No. PB-31: 1mg \$US 200.00
Cat. No. PB-35: 5mg \$US 700.00

Photobiotin Labelling and Detection Kit—Cat. No. PBK-3: \$US 130.00
(Contains 200 µg Photobiotin,
Avidin-Alkaline Phosphatase, BCIP, NBT)

Full details supplied with each package.

AUTUMN SHOWCASE

Molecular Mechanisms of Transmembrane Signalling

Molecular Aspects of Cellular Regulation, Volume 4

edited by P. Cohen and M. D. Houslay

Over the past few years great strides have been made in the characterisation and purification of receptors and in elucidating the mechanisms by which extracellular signals, acting through receptors, regulate transmembrane signalling systems that control production of second messengers within the target cells. This book highlights the recent impressive advances in this area, which have led to the emergence of unifying concepts, and the linkage of areas in biology that were previously thought of as being quite separate.

Immunotoxicology of Drugs and Chemicals

edited by J. Descotes

"Immunotoxicology" has been set up as an updatable handbook series, the contents of which will cover developments in the understanding of principles of immunotoxicology and detailed accounts of immunotoxic properties of bioactive substances as reported in the scientific literature. The purpose of the series is to assemble and evaluate critically all present knowledge in the above-mentioned area, and to act as a continuing, up-to-date and complete source of reference for immunotoxicologists worldwide.

Practical Methods in Electron Microscopy

edited by Audrey M. Glauret

Volume 11

Thin foil Preparation for Electron Microscopy

by P. J. Goodhew

This comprehensive volume covers all the commonly-used techniques for preparing thin specimens for transmission electron microscopy in material science. Full descriptions are given of both simple laboratory techniques and sophisticated commercial thinning equipment for electropolishing, ion beam milling and replica making.

All the stages involved in the production of a thin foil from a large piece of metal, ceramic, polymer or semi-conductor are described.

Low Temperature Methods in Biological Electron Microscopy

by A. W. Robards and U. B. Sleyter

The present trend towards the collaboration of biologists, physicists, engineers and, not least, commercial people means that low temperature methods will become more effectively, more widely and more easily available.

This book does not and cannot exclusively present well tried and tested methods. Rather, it attempts to pursue a middle course whereby the reader is not only made aware of what can be done but is also informed of background details so that, as the subject develops further, he or she will

have the scientific basis upon which to build. The purpose is to paint the background against which future developments will take place. The book tells the reader both how to choose and implement different methods as well as why. It also attempts to provide an adequate gateway into the literature so that those who wish to extend their knowledge further will be able to do so.

Long-Term Monitoring in Epilepsy

edited by J. Gotman, J. R. Ives and P. Gloor

EEG Supplements vol. 37

This volume presents the many different ways of monitoring, as well as explaining the reasons for using this complex procedure. The clinical applications covered, includes the localization of epileptic foci, the differential diagnosis of epilepsy, the action of antiepileptic drugs, the interaction of sleep and epilepsy, the particular problems of infants and children, and the management of status epilepticus.

This volume is the first complete review of the new multidisciplinary area of monitoring epilepsy and will prove to be extremely valuable to those who are considering setting up or improving monitoring facilities, as it will give them the background information to make an enlightened choice of equipment and guide them in the indications, benefits and limitations of monitoring epileptic patients.

Keeping science at the core

Harvey Brooks

The Education of a College President: A Memoir. By James R. Killian, Jr.
MIT Press: 1985. Pp.478. \$19.95, £19.95.

DURING the middle years of this century, James Killian presided over the transformation of the Massachusetts Institute of Technology from a highly respected engineering school to the world's leading technological university, a "university polarized around science". This last phrase is used by the author to describe an institution embracing virtually all fields of knowledge, but with each discipline in orbit, as it were, around a central nucleus of science and technology. In the same career, Killian intermingled university leadership with high-level public service, notably as science adviser to President Eisenhower and as a key figure in many seminal government advisory groups during a formative period for both science policy and defence policy. What were the experiences and personal qualities that enabled this individual, not himself either a scientist or an intellectual with academic pretensions, to become accepted as a colleague and leader by scientists and scholars, and to become an educational and scientific manager of the first rank? This highly personal, rambling and optimistic memoir does provide some insight into the answers, though it is as interesting for what it leaves out as for what it includes.

A man of broad general culture, boundless intellectual curiosity and catholic interests, very "people oriented": though not remarkably gregarious, Killian became dedicated through an unusually varied apprenticeship to "developing creative integration and interdisciplinary congeniality among a variety of research fields", and he applied an extraordinary talent for consensus-building among diverse and strong-minded individuals in both academic and political settings. He was obviously a good listener with a capacity for extracting a practical synthesis out of the ideas of creative people. Not an obvious originator himself, and lacking a strong pride in authorship, he nonetheless had a talent for recognizing people with original ideas and enabling them to realize their visions.

His success in these endeavours was reinforced by what he describes as his "clinging to a melioristic view that our future is best served by an acceptance of what Sir

Peter Medawar has aptly termed 'the hope of progress' ". This attitude, he felt, came from his "having lived so long in the regenerative sanctuary of a research university" with a "singular fellowship of young men and women working in a contagious atmosphere of excellence, discovery, and high spirits" (p. 415). He had a knack for

persuade the disciplines to subordinate their parochial interests and claims to academic "turf". Thus he sees MIT as a federal rather than as a feudal system. I suspect one could find a good many people at MIT who would not fully share this view, but I think it is, on average, correct.

Killian cites two revealing anecdotes to illustrate the source of his view of the key importance of consensus-building. Each involved the eventual failure or compromise of a good idea because of a lack of consultation with powerful interests in advance of a public commitment. The first example is an academic one. In 1956, at a public dinner in New York, he announced MIT's intention to establish within its structure a new School of Advanced Study before he had spoken to the appropriate faculty committees or the faculty as a whole. From the incident he drew a lasting lesson that "no new programs or buildings large in costs should be undertaken, however innovative, without the knowledge and advice of appropriate faculty groups" (p.138). In this instance, what he still obviously feels was an excellent idea had to be abandoned.

A parallel example on the national stage occurred soon after Killian had become science adviser to Eisenhower. In 1958, on the basis of the technical findings of the President's Science Advisory Committee, communicated to him by Killian, Eisenhower wrote to Khrushchev suggesting that a comprehensive nuclear test ban agreement was negotiable, and proposing the convening of a panel of technical experts to agree upon the design of an international detection system capable of ensuring against clandestine testing — especially underground testing — by any nation. The President's initiative, however, was taken without internal consultation with the Department of Defense, The Atomic Energy Commission or the Central Intelligence Agency.

Of the technical discussions, led on the American side by Dr James B. Fisk, President of Bell Laboratories, Killian says: "Dr. Fisk and I agreed that at no subsequent negotiation with the Soviets on arms limitation had the Soviets expressed such willingness to accept on-site inspection" (p.281). He implies that the lack of internal consultation in the US government before the Presidential initiative "was to aggravate differences in our own government" which became a major factor in America's inability to negotiate a comprehensive test ban rather than the much more limited atmospheric test ban finally achieved under the Kennedy administration in 1963. As we now know, the

James Killian on the cover of *Newsweek*, November 18 1957.

helping brilliant — often cranky and egotistical — people to sell themselves and their ideas, and he believed this could best be accomplished through conscientious and patient consultation.

Insofar as MIT was concerned, Killian rejects Clark Kerr's pessimistic view of the modern "multiversity" impervious to structural change, the advocate of change for every part of society except itself. The MIT he knew originated and assimilated many structural improvements, including new interdisciplinary laboratories, curriculum reform, undergraduate research, a new management school, new departments in the humanities and social sciences, a joint school of health sciences and technology with Harvard, and many other institutional innovations. MIT, Killian feels, has avoided the usual "hang-ups" of the multiversity by combining a single unified faculty with a strong, but accessible, style of presidential leadership, able to

rapid evolution of a sophisticated technology for underground tests largely offset the constraints on weapons development posed by the ban on atmospheric testing, and really only served to drive nuclear weapons development underground — literally and figuratively — and out of the public eye. Whether prior consultation would have merely tied the hands of the technical negotiators rather than leading to a stronger diplomatic agreement is a matter of opinion. But again, Killian's account of this episode illustrates the high importance which he attached to the building of consensus among divergent interests as a prerequisite for action (p. 279).

Although Killian's assessment of the achievements of the modern research university is highly positive, and in many

the quality of engineering and is this in turn a consequence of deterioration in the standards of engineering education? Were the reforms of the engineering curriculum to make it more "scientific" and general, which Killian obviously endorses, implicated in the problem, as some people are now asserting? Did the American preoccupation with originality, creativity and individual competitive achievement somehow result in neglect of meticulous workmanship and attention to the more routine and mundane aspects of engineering, which are so crucial to the quality and reliability of technological products? Did the great research universities, in their pursuit of a particular cultural concept of "excellence", provide an inappropriate model for the mass of the engineering and technical professions?

James Killian (second from right) with Philip Morse, Vannevar Bush and Thomas J. Watson dedicate MIT's first major computational centre in 1957.

ways forms the *leitmotif* for his whole memoir, he does concede some shortfalls and failures; however, he makes little effort to analyse the possible reasons for them. For example, while he is proud of MIT's success in creating interdisciplinary laboratories and in fostering other kinds of creative work across conventional intellectual boundaries, he admits that MIT's efforts "have not succeeded in demonstrating how these fields necessarily interact with each other and how this diverse learning is comprehended in indivisibility" (p. 402). Somehow his "enlarged vision of the place" has not quite been achieved. Yet he never even speculates as to the reasons why this might have been so.

More seriously, he suggests that the universities cannot wholly disclaim responsibility for an unmistakable decline in the quality of everyday life as so frequently reflected in American craftsmanship, in the unreliability of too much of our technology, and in the low quality of many consumer products and their service [p. 410].

This is an intriguing statement, which is simply left hanging. In what way or in what sense are the universities responsible? Does the situation reflect a decline in

Another intriguing area of ambivalence in Killian's account of the era he describes has to do with the role of the "military-industrial complex". On the one hand, the whole memoir is full of pride in the services of MIT and its staff (including Killian himself) to the nation in matters of national security — the series of interdisciplinary studies organized by MIT in the 1950s, the creation of the Lincoln Laboratory, the accomplishments of the Instrumentation Laboratory (now divested from MIT as the Draper Laboratory), Project Whirlwind, the Servomechanisms Laboratory and so on. On the other hand, he makes frequent references to the dangers of militarization, stating in one place that "the military-industrial complex . . . is still having a profoundly dangerous impact on our government" (p. 419). Even his "hope of progress" is "tempered . . . by fear of nuclear war and of an intemperate militaristic spirit eroding the most precious values of our society" (p. 415).

These are strong words, but just who is the military-industrial complex? Many of the basic technological advances that have helped fuel the arms race have emerged from the large government-financed laboratories managed and operated by some

of our great research universities — for example, the concept of multiple independently targeted re-entry vehicles and dramatic advances in missile guidance accuracy that emerged from the MIT Instrumentation Laboratory, and the high yield-to-weight thermonuclear weapons which were developed in the two weapons laboratories of the University of California. While praising the scholars from research universities who "have been speaking with knowledge, integrity, and responsibility about nuclear issues" (p. 419), Killian never quite comes to grips with what the proper role of the research universities should be in relation to the creation of military technology or even the science underlying it. Should research universities, for example, pick and choose which governmental demands they respond to according to some collective view of their potential effect upon the arms race? What would be the implications for academic freedom of the enforcement of such a collective sense of responsibility on their individual members? To what extent would such institutional self-denial decrease the capacity of academics to speak out with real knowledge and responsible criticism in the national debates over defence policy, and leave the field to those with greater vested interests than the universities? These issues have never been posed to the universities in starker form than by the current Strategic Defence Initiative; it would have been interesting to have had Killian's views as to how his favourite institutions should come to grips with this new challenge to their role.

The sanguine tone of this memoir sometimes borders on the Pollyanna-ish. It is striking that, although there are interesting personal sketches of many of the principal actors in the development of America's post-war science and defence policies, villains are notable by their absence. Admiral Lewis Strauss of the Atomic Energy Commission is virtually the only important personality even mentioned in unfavourable terms, and even here the strictures are remarkably restrained. The vehement denunciations of the military-industrial complex are notable for their lack of specificity, and the reader is left in the dark as to which institutions and groups qualify for this pejorative label, and what sorts of behaviour take them over the line from patriotism to villainy. Lobbying of the political process on behalf of funding for particular weapons systems seems to be the only identified behaviour which is beyond the pale, yet one must also ask how these activities are to be distinguished from the various "summer studies" and high-level commissions (such as the Technological Capabilities Panel, which Killian himself chaired) which were the genesis of many new weapons systems.

Harvey Brooks is Benjamin Peirce Professor of Technology and Public Policy, John F. Kennedy School of Government, Harvard University, Cambridge, Massachusetts 02138, USA.

Chatting fractals and New Math

Thomas Banchoff

Mathematical People: Profiles and Interviews. Edited by Donald J. Albers and G.L. Alexanderson. *Birkhäuser*: 1985. Pp.372. \$24.95.

GEORGE Pólya died recently at the age of 97. Here was a legendary teacher whose book *How to Solve It* and famous film *Let Us Teach Guessing* inspired generations of students and teachers of mathematics. Would it not have been instructive to have had the opportunity to ask him questions about his career? In recent years, Benoit Mandelbrot's filigreed fractal patterns have burst out of the pages of journal after journal, intriguing scientist and designer alike. How would it be to interview him and get some insight into the process of creating a new kind of mathematics?

In *Mathematical People* we can enjoy conversations with these figures and two dozen more. This collection of interviews and profiles comes primarily from a very successful series of articles over the past six years in *The College Mathematics Journal* (formerly *The Two-Year College Mathematics Journal*). The project began auspiciously with an interview with Pólya on the occasion of his ninetieth birthday celebration at Stanford and continued to include some of the most interesting mathematical people of our day.

Here are stories about Persi Diaconis, who left school at 14 to travel with a professional magician, Martin Gardner who explains the origin of his hugely popular *Scientific American* column, and the immensely prolific, champion collaborator Paul Erdős. We can follow the controversial views of Morris Kline about the New Math, and compare them with the counter-suggestions of Peter Hilton and Paul Halmos. We can contrast the impressions of Richard Courant given by his co-author Herbert Robbins and by the biographer Constance Reid. And we can keep track of dozens of comments about the sometimes opposing relationships between pure and applied mathematics.

What we do not find are answers to the question: "What good is mathematics anyway?" The interviewers are for the most part mathematicians themselves and everyone takes for granted the fact that the creation and communication of mathematics is a worthwhile occupation. Moreover the primary readership for the original articles was teachers of mathematics, so questions tend to centre on different aspects of teaching as opposed to research.

There is wide variation in the depth and the nature of the interviews and profiles, and occasionally a general reader will be left behind when the discussion takes a

technical turn. There are also a few other places where one looks in vain for a follow-up to a remark in an interview. For example, what was the subject of Donald Knuth's first published article, in *MAD Magazine*? Could Albert Tucker please explain why his mentor Solomon Lefschetz had artificial hands? And if David Blackman was not conscious of discrimination all through his schooling, why was it that he only applied to black institutions when he sought his first job?

By and large, however, the interview format is quite successful. By contrast the set pieces taken from popular scientific journals, on Shiing-Shen Chern and Ron

Ivor Grattan-Guinness

Mathematics and the Search for Knowledge. By Morris Kline. *Oxford University Press*:1985. Pp.257. \$19.95, £21.

OVER several decades, Morris Kline has built up an enviable reputation as the author of a series of popular books on mathematics which include a substantial element of historical material. The first book, *Mathematics in Western Culture* (Oxford University Press, 1953), remains perhaps the best: the last one, *Mathematics: The Loss of Certainty* (Oxford University Press, 1980), was probably the worst, with numerous infelicities and errors over the foundations of mathematics and its history. This latest volume lies somewhere between the two.

Here, Kline has returned to applied mathematics, in order to explain how mathematics helps us to understand the physical world. After a "Historical Overview" dealing with various philosophers' positions on the possible existence of an external world, and a discussion of the fallibility of sense perception, he proceeds to a chronological account of episodes in the history of astronomy and mechanics: the Greeks, Copernicus and Kepler, Descartes and Newton. Then electromagnetism is introduced, chiefly as background to relativity and quantum mechanics. The final trio of chapters contains discussions of aspects of the philosophical questions which underpin the book as a whole.

The level of success achieved by Kline in answering these questions may be appraised at first by looking at his use of history. The treatment is more detailed than in his *Mathematics and the Physical World* (Crowell, 1959), but not much; in particular, there is not actually a great deal of mathematics in the book, the chapters on general relativity and quantum mechanics including hardly any at all. Further, the range of applications is curiously incomplete: there is little or nothing on optics, heat diffusion (the paragraph on p. 202 about Fourier mis-

Graham for example, may be better organized and generally more informative but they lack the spontaneity of the transcribed interviews. The detailed and technical autobiographical reminiscence of Olga Taussky-Todd, originally written as part of a Caltech oral history project, seems out of place in this volume.

Still, one must expect such vagaries in a collection such as this. Many people will find illumination and entertainment in the book, and will be happy to learn that a second volume is in preparation. □

Thomas Banchoff is Professor of Mathematics at Brown University, Providence, Rhode Island 02912, USA.

represents his philosophy, overrates his mathematics and underrates his physics), hydrodynamics, elasticity theory or engineering mathematics (friction studies, machines of all kinds, cartography and topography, and so on). Probability and statistics earn the falsehood that "the theory of probability . . . entered into mathematics quite by chance in connection with games of chance" (p. 189): the virtual absence of these two topics is an especial pity, since work on them greatly extended the range of application of mathematics and raised important questions about knowledge and ignorance, and the epistemological status of approximate theories.

The result of these omissions is not only

Vaulting Ambition

Sociobiology and the Quest for Human Nature

PHILIP KITCHER

**'The best dissection ever published
of the logic and illogic (mostly
the latter) of sociobiology.'**

Stephen Jay Gould

Vaulting Ambition is indeed the last word on the subject of sociobiology. It is meticulous in its argument and total in its scope. It deals a carefully reasoned blow to the pretensions of sociobiologists.' *Richard Lewontin*

Reader Service No 21

that many essential historical episodes have been passed over, but also that certain crucial aspects of the ways in which mathematics aids our search for knowledge are absent. The terms within which the subject has been tackled are too modest, a failing which also applies to the weight of supporting mathematical apparatus which is brought to bear. There is, for example, no discussion of the calculus, so that the "mathematicization" of continuous media and phenomena cannot be described properly. The clash between different mathematical styles is not

A Julia set and its interior for the map $z \rightarrow z + i|z|$. Taken from *Mathematical People* (see previous review).

brought out, especially between the geometrical (where the properties of the given configuration play a role) and the algebraic (where formal manipulations of general basic formulae are executed, with deliberate avoidance of geometrical processes); analytical and topological styles bring further differences in their train. Finally, the extent to which a mathematical expression (in any style) reflects the structure of the physical context in which it is used is a matter which should have loomed large, but it does not.

All of these questions involve issues about mathematical proofs, which receive little attention here. But proofs lie at the heart of much of the development of mathematics and thus of its role in the "search for knowledge". The posing of such questions would have served Kline's cause better than the pastiche accounts of philosophers' views on the external world which he does provide (but which have no special bearing on the use of mathematics). This book is best taken as another example of his ability to write breezy and readable surveys of the history of mathematics, and to tackle the philosophical background on the wing; as a contribution to the problem raised, however, *Mathematics and the Search for Knowledge* is merely a propaedeutic. □

Where lies the science?

Anthony W. Clare

The Psychoanalytic Movement. By Ernest Gellner. *Paladin*: 1985. Pp.241. Pbk £3.50.

Psychoanalysis and Beyond. By Charles Rycroft. Edited by Peter Fuller. *Chatto & Windus*: 1985. Pp.310. Hbk £10.95; pbk £4.95. To be published early next year in the United States by Chicago University Press.

Psychoanalysis: Freud's Cognitive Psychology. By Matthew Hugh Erdelyi. *W.H. Freeman*: 1985. Pp.303. Hbk \$24.95, £25; pbk \$14.95, £14.95.

Decline and Fall of the Freudian Empire. By Hans Eysenck. *Viking*: 1985. Pp.224. £12.95.

THE way in which the psychoanalytic school was formed raises profound questions concerning its status as a science and suggests that it might, with benefit, be viewed as a secular religion. Certainly, one will look in vain elsewhere in science for another example of a body of theoretical knowledge linked so intrinsically, so inextricably, with the individual who first propounded it. In no other branch can one find an absence of an external arbitrator, that is to say someone outside the control of the system itself and able to pass independent comment on its claims, achievements and shortcomings. In the case of psychoanalysis, the location of the criterion of its truth is, in the words of Ernest Gellner, "determined by the ideas of the system itself; the well of truth is within the ramparts and not outside". The possession of this truth is not handed down in seminars and courses of instruction, though these play a small part, but by way of participation in the training analysis. As the apostolic succession from St Peter is handed down from the bishops to newly ordained priests, so the authentic link with Freud is maintained and continued by means of the transfer of authority from training analyst to analysand.

The religious analogy does not end there. As intellectual and rational criticism of revealed religious dogma is interpreted as a closing of the mind and heart to truth, and in no way a valid comment on the basic validity of the truth itself, so criticism of psychoanalysis is rejected on the grounds that either the critic has never been analysed, in which case he is resisting the need to be analysed (which itself is worthy of interpretation), or he has been analysed and his criticisms reflect an incomplete or prematurely terminated process, the result no doubt of fear over what might be revealed. And the religious analogy becomes uncomfortable when one examines the schisms and factions within the domain of psychoanalysis, with each school claiming to have adhered the

closest to the spirit as well as the law laid down by the supreme founder.

The question which Gibbon asked of Christianity is equally applicable to psychoanalysis: by what means did the new vision obtain so remarkable a victory? In a stylish, witty and deceptively readable book, Gellner exposes the secular religious nature of the psychoanalytic enterprise. He admits that a compelling, charismatic belief must possess more than merely the promise of succour in a plague and links with the background convictions of the age. It must engender a tension in the neophyte or potential convert. It must tease and worry him with its promise and its threat. The doctrine to be embraced must contain the promise of a salvation that is earnestly desired. There must be plausible reasons for believing its claims and also good reasons for doubting it or fearing its truth. The middle ground between acceptance and rejection must be denied and the issue of whether it is or is not true must be trans-empirical and untestable. The fact that confidence in psychoanalysis is devoid of any visible means of support hardly seems to diminish its authority: indeed, argues Gellner,

were its means of support visible, they would be subject to evaluation; and the assertion would have given hostages to fortune, and also conceded its own ordinary, human status — making its own contentions arguable, negotiable, imitable, publicly available rather than tied to a single source.

One psychoanalyst who has been particularly conscious of the contentiousness of the psychoanalytical factions is Charles Rycroft who, in so far as he identifies with any particular school, tends to align himself with the English-speaking school uniting such disparate practitioners as Winnicott, Fairbairn, Balint and Bowlby. This group, as Rycroft pointed out in an essay entitled "Psychoanalysis and Beyond", contained in the collection of his writings under the same title, repudiated any royal road to becoming an analyst even to the extent of encouraging trainees to have part of their teaching under the supervision of a member of another faction. Rycroft underwent, as far as one can tell, an orthodox Freudian analysis and in 1956 presented a paper to the British Psycho-Analytical Society which challenged the prevailing theory of symbolism by suggesting that it is not a regressive or defensive phenomenon but rather "a general capacity of the mind" which could be deployed in manifold different ways. According to Peter Fuller, the editor of the book, the Society received this modification, the first serious one advanced to a theory of some 40 years standing, with reserve while it struggled to protect the orthodox position. It was the first of a number of theoretically awkward questions that Rycroft was to raise, on such issues as dreams, fantasies and the nature of psychoanalysis itself.

In 1968, he wrote *A Critical Dictionary*

BIOLOGY OF THE REPTILIA Volume 14: Development A

edited by **C. Gans**, *University of Michigan*, **F. Billett**, *University of Southampton*, and **P.F.A. Maderson**, *University of London*

Volume 14 begins to characterize the developmental patterns exhibited by reptiles. It covers vertebrate development not only in relation to the molecular mechanisms controlling it, but also in terms of such classical areas as neoteny, organogenesis and regeneration of the parallel shift of structure and function during ontogeny, as well as of comparative and evolutionary approaches.

Contents: Why Study Reptilian Development?; The Origin and Development of Oocytes; Embryology of Turtles; Embryology of Marine Turtles; Development of Crocodilians; Embryology of the Tuatara; Some Developmental Problems of the Reptilian Integument; Reptilian Immunity; Development of the Pituitary in Reptiles; Author and Subject Indexes.

THE EVOLUTION OF GENOME SIZE

edited by **T. Cavalier-Smith**, *Department of Biophysics, University of London*

Do the massive amounts of 'extra' DNA in organisms like some salamanders and lilies that have exceptionally large genomes have some function? If so what? Or is the extra DNA merely useless junk or a 'selfish' parasite ('selfish DNA') of the cells replication machinery? This is the first complete book entirely devoted to these problems. It discusses both the evolutionary causes and the molecular mechanisms of changes in genome size. It emphasises the universal positive correlation between genome size and cell volume, and discusses both natural and experimentally induced changes in genome size.

0471 10272 5 534pp October'85 £38.50

THE BIOCHEMISTRY OF THE POLYPEPTIDE HORMONES

by **M. Wallis**, *School of Biological Sciences, University of Sussex*, **S.L. Howell**, *Department of Physiology, Queen Elizabeth College, University of London* and **K.W. Taylor**, *Department of Biochemistry, London Hospital Medical School*

The Biochemistry of Polypeptide Hormones is intended to meet the needs particularly of advanced undergraduates, preclinical students and postgraduates, and provide an introduction to the research literature. All the main groups of polypeptide hormones are covered, and special chapters deal with structure-function relationships, hormone receptors, the role of second messengers and the applications of recombinant DNA technology. The authors have wide experience in teaching biochemical endocrinology to undergraduates and postgraduates in biochemistry, physiology and medicine, and the book provides a companion text to courses of this kind. It is also intended to be a useful introduction to graduates entering the field of hormone biochemistry from other disciplines.

FORESTRY HANDBOOK, Second Edition

edited by **K.F. Wenger**

A revised and reorganized practical reference for the working field forester, incorporating the latest information and new, improved methods in such critical areas as U.S. forest law and policy, forest taxation, cost accounting and accomplishment reporting, pesticide and environmental aspects, safety, and public involvement procedures.

0471 06227 8 1,358pp May'84 £51.10

MYCOTOXINS Formation, Analysis and Significance

by **J.E. Smith**, *Department of Bioscience and Biotechnology, University of Strathclyde* and **M.O. Moss**, *Department of Microbiology, University of Surrey*

Discussed in this book, are the nature, origin, activity and control of the poisonous metabolites of moulds known as mycotoxins. This important area of applied mycology has ramifications throughout the world and it is essential that a fundamental understanding of the nature of mycotoxins should be widely disseminated so that rational judgements can be made when society is faced with problems of contaminated food and animal feeds. The basic science (mycology, biochemistry, chemistry and agriculture) is provided, but the book emphasises the multidisciplinary nature of research on disease and illness caused by mycotoxins and attempts to relate both to the applied aspects of analysis, control and diagnosis.

0471 90671 9 154pp October'85 £14.95

FUNDAMENTALS OF INSECT PHYSIOLOGY

by **M.S. Blum**, *University of Georgia*

A carefully organized and written textbook and state-of-the-art survey of the physiology of insects, with comprehensive referencing to take the reader into the literature. The book discusses the circulatory, digestive, excretory, respiratory, muscle, nervous, reproductive and exocrine systems and also the integument, behavioral physiology, intermediary, metabolism and hormonal aspects of development.

0471 05468 2 614pp October'85 £46.20

NUTRIENT CYCLING IN TROPICAL FOREST ECOSYSTEMS Principles and their Application in Management and Conservation

by **C.F. Jordan**, *Institute of Ecology, University of Georgia, USA*

Interest in tropical ecology has increased in recent years, due partly to the worldwide publicity given to increasing rates of tropical deforestation. There is much current concern about the effect of deforestation on productive potential and resilience of tropical forest ecosystems, because of increasing evidence that most tropical soils are much less fertile, and more easily leached and eroded than temperate zone soils. This book addresses these concerns by bringing together much of the recent literature on nutrient cycling in tropical forests, and changes in the cycles following conversion to croplands, pastures, and plantation forests.

NEW·AUTUMN·TITLES

THE ATLANTIC ALCIDAE

Edited by D.N. Nettleship and T.R. Birkhead

1985, 600pp., \$19.95/£17.50 (UK only), ISBN: 0.12.515671.5 Pbk
\$40.00/£35.00 (UK only), ISBN: 0.12.515670.7 Hbk

Contents: Evolution and characteristics of the Atlantic Alcidae, J. Bedard. Distribution and status of the Atlantic Alcidae, D.N. Nettleship and P.G.H. Evans. Breeding ecology of the Atlantic Alcidae, M.P. Harris and T.R. Birkhead. Ecological adaptations for breeding in the Atlantic Alcidae, T.R. Birkhead and M.P. Harris. Population parameters of the Atlantic Alcidae, P.J. Hudson. Feeding ecology of the Atlantic Alcidae, P.J. Hudson. Feeding ecology of the Atlantic Alcidae, M.S.W. Bradstreet and R.G.B. Brown. Development of the young in the Alcidae, A.J. Gaston. Coloniality and social behaviour in the Alcidae, T.R. Birkhead. The Atlantic Alcidae at sea, R.G.B. Brown. Conservation of the Atlantic Alcidae, P.G.H. Evans and D.N. Nettleship.

FORM AND FUNCTION IN BIRDS

Volume 3

Edited by A.S. King and J. McLelland

1985, 470pp., \$99.50/£86.50 (UK only), ISBN 0.12.407503.7

Volume 3 of this major four volume series focusses on topics related to locomotion and the special sense organs. The purpose and high standard of the first volumes is maintained, the emphasis being on the close relationship between anatomy and adaptation to function in the various systems described. Not confined to domestic species, numerous, clear and beautiful illustrations help to show how and why birds are built as they are.

FISH IMMUNOLOGY

Edited by M.J. Manning and M.F. Tatner

1985, 374pp., \$32.50/£27.00 (UK only), ISBN 0.12.469230.3

As fisheries biologists turn to immunologists to help solve problems of disease control in the aquaculture industry fish immunology is becoming a discipline in its own right. This book presents a topical, comprehensive review of current research and exciting progress in the field.

IMPLANTATION OF THE HUMAN EMBRYO

Proceedings of the Second Bourn Hall Meeting

Edited by R.G. Edwards, J.M. Purdy and P. Steptoe

1985, 475pp., \$59.50/£52.00 (UK only), ISBN 0.12.232455.2

Human implantation was chosen for the topic of this Second Bourn Hall meeting, because knowledge about it has been scarce and difficult to obtain. This book covers the scientific and clinical aspects of the subject with a thoroughness which will make it as useful and as timely as the previous volume.

It will be a vital purchase for IVF clinicians, endocrinologists, gynecologists specialising in infertility and basic research workers.

Contents: Part 1, Follicular stimulation and the Corpus Luteum. Part 2, The Uterus. Part 3, Embryo-Uterine Interactions. Part 4, Luteolysis. Part 5, Clinical Aspects of Human Implantation. Part 6, Pregnancy and Birth.

THEORETICAL BIOLOGY AND COMPLEXITY

Three Essays on the Natural Philosophy of Complex Systems

Edited by R. Rosen

1985, 224pp., \$55.00/£48.00 (UK only), ISBN: 0.12.597280.6

FROM THE PREFACE: This volume is made up of three short essays, each separately conceived and written, each with distinct thrusts and emphases, but nevertheless closely related in substance and spirit.

RATES OF PHASE TRANSFORMATIONS

R.H. Doremus

1985, 192pp., \$29.00/£26.00 (UK only), ISBN: 0.12.220530.8

The fundamentals of the kinetics of phase transformations are presented in this volume. The author integrates reviews of current knowledge with theory, experiments, and references to provide a clearly written introduction to this complex subject.

THE DOSIMETRY OF IONIZING RADIATION

Volume 1

Edited by K.R. Kase, B.E. Bjärnagard, and F.H. Attix

1985, 440pp., \$34.95/£31.00 (UK only), ISBN: 0.12.392651.3 Pbk
\$69.50/£60.50 (UK only), ISBN: 0.12.400401.6 Hbk

This first volume of THE DOSIMETRY OF IONIZING RADIATION reviews current methodology and theory of radiation measurement and dosimetry and is designed to supplement the three-volume *Radiation Dosimetry, Second Edition*.

THE RECEPTORS

Volume 2

Edited by P. M. Conn

1985, 456pp., \$65.00/£56.50 (UK only), ISBN: 0.12.185202.4

THE RECEPTORS reports current results of receptor research in a wide range of disciplines – pharmacology, endocrinology, biochemistry, cell biology, and neuroscience.

CONTROL OF ANIMAL CELL PROLIFERATION

Volume 1

Edited by A.L. Boynton and H.L. Leffert

1985, 576pp., \$68.50/£60.50 (UK only), ISBN: 0.12.123061.9

Volume 1 of this two-volume treatise updates various areas of animal proliferation, beginning with trends and issues (oncogenes and stems). Current knowledge of the structure and function of several growth factors and their receptors and of the mechanisms of information transduction are reviewed. Finally, certain aspects of DNA structure, DNA regulation, protein synthesis, and mitosis are presented.

IRON FORTIFICATION OF FOODS

Edited by F.M. Clydesdale and K.L. Wiemer

1985, 192pp., \$36.50/£32.00 (UK only), ISBN: 0.12.177060.5

Iron deficiency anemia is the world's most prevalent nutritional problem. This volume analyzes the problems encountered in treating anemia through iron fortification of staple foods, beverages, condiments, and salt.

MONOCLONAL ANTIBODIES AGAINST BACTERIA

Volume 1

Edited by A.J.L. Macario and E. Conway de Macario

1985, 336pp., \$45.00/£39.50 (UK only), ISBN: 0.12.463001.4

FROM THE PREFACE: The major aim of this multivolume treatise is to assemble contributions in the field of bacterial immunology focused on monoclonal antibodies. The contributions are, for the most part, first attempts at reviewing data and publications in specific, restricted areas.

P&S Biomedical Sciences Symposia Series

CELL BIOLOGY OF THE MAJOR HISTOCOMPATIBILITY COMPLEX

Contents: Background: Radioactive Wastes. Radwaste Disposal. Earth Science Perspectives: The Earth's Crust. Geological Time. Surface Processes: Biogeochemical Aspects. Surface Processes: Denudation and Deposition. Sedimentary Rocks: Formation and Properties. Volcanic Processes and Products. Natural and Synthetic Crystalline Rocks. Physical Processes in the Upper Crust. Fluid/Rock Interactions. Ocean Processes. Climatic Change and Continental Glaciation. Application: Predictive Geoscience. Repository Site Selection. Index.

Studies in Archaeological Science Series

THERMOLUMINESCENCE DATING

M.J. Aitken, F.R.S.

1985, 351pp., \$34.95/£31.95 (UK only), ISBN: 0.12.046381.4 Pbk
\$59.00/£50.00 (UK only), ISBN: 0.12.046380.6 Hbk

This book provides an authoritative account of the theory and practice of thermoluminescence dating and comes with extensive tables and technical notes. Whilst aimed primarily at practitioners it is intended also as a reference point for all those in archaeology and quaternary research who are utilising TL dates and need to be aware of the constraints and capabilities of the TL technique.

Contents: Introduction: Basic Pottery Dating. Thermoluminescence. Natural Radioactivity: The Annual Dose. Artificial Irradiation. Special Methods. Beyond Pottery. Sediment Dating - Solar Resetting.

Linnean Society Symposium Series No.11

ECOLOGY AND GENETICS OF HOST-PARASITE INTERACTIONS

Edited by: D. Rollinson and R.M. Anderson

1985, 280pp., \$45.00/£35.00 (UK only), ISBN: 0.12.593690.7

Much interest has been focused recently on the co-evolution of parasites and their hosts, particular emphasis being given to understanding the selection pressures involved in host-parasite interactions. This book reflects the growing interest in research at the interface between population, ecology and population genetics and highlights recent progress in this important area of biological research, which has many implications for disease management in human and veterinary medicine.

POPULATION DYNAMICS OF RABIES IN WILDLIFE

Edited by P.J. Bacon

1985, 349pp., \$29.95/£27.50 (UK only), ISBN: 0.12.071351.9 Pbk
\$58.00/£50.00 (UK only), ISBN: 0.12.071350.0 Hbk

Following a general introduction to the biology of the disease and its hosts, this book examines a variety of models which try to explain the disease's epidemiology. Using simple mathematics the strengths and weaknesses of the various models, and thereby of our own understanding of rabies, are clearly illustrated. The results of these analyses have interesting implications for the choice of control strategies most likely to succeed. This book will interest not only those working on rabies, but anyone with an interest in spatial population processes and their interaction with disease dynamics.

Principles, Applications & Regulations of Biotechnology in
Industry, Agriculture and Medicine

Editor-in-Chief: MURRAY MOO-YOUNG, *University of Waterloo, Canada*

The Most Authoritative, Multidisciplinary, Multipurpose Reference Work on Biotechnology

- ★ Over 3500 large format pages (272x188 mm) in four handsomely bound volumes
- ★ Indispensable to manufacturing and service industries, particularly those involved with pharmaceuticals, foods and beverages, fuels, chemicals, waste treatment, agriculture, mining and medicine
- ★ Important new developments in the legal, regulatory and international aspects of biotechnology are included
- ★ Written by over 250 of the world's foremost scientists and engineers in biotechnology, from 15 countries, under the direction of internationally renowned editors
- ★ Systematically arranged for easy access by both general and specialized scientists and engineers
- ★ All information regularly updated by the Pergamon review journal *Biotechnology Advances*
- ★ Volumes 1 and 2 present the *unifying, multidisciplinary principles of biotechnology in terms of scientific and engineering fundamentals*
- ★ Volumes 3 and 4 describe the *applications of biotechnology principles in the various manufacturing and service practices in industry, government and business*
- ★ Volumes 1-3 *separately indexed and a cumulative index* is contained in Volume 4. *A detailed glossary of terms helps the beginner in the various areas of the field*

Of special interest to:

Chemical engineers and biochemical engineers who require information on mass and energy balances and rates of processes, including fermentations, product recovery and feedstock pretreatment, and the equipment for carrying out these processes

Biologists, microbiologists and molecular biologists who require information on the biological characteristics of living organisms involved in biotechnology and the development of new life forms by genetic engineering techniques

Environmental engineers and sanitary engineers who require information on biological waste treatment methods and equipment, and on contamination potentials of the air, water and land within the ecosystem, by industrial and domestic effluents

Chemists and biochemists who require information on the chemical characteristics of enzymes, metabolic processes, products and raw materials, and on the basic mechanisms and analytical techniques involved in biotechnological transformations

Health scientists, nutritionists and toxicologists who require information on biohazards and containment techniques, and on the quality of products and by-products of biotechnological processes, including the pharmaceutical, food and beverage industries

Administrators, executives and legal & investment advisors who require information on national and international governmental regulations and guidelines on patents, environmental pollution, external aid programs and the control of raw materials and the marketing of products

Over 3500 pages 8000 lit refs approx Winter 1985 Prices subject to change without notice.

Headington Hill Hall, Oxford OX3 0BW, UK
Fairview Park, Elmsford, New York 10523, USA

of *Psychoanalysis*, a task which enabled him to take all the current psychoanalytical theories and systems to pieces and compelled him to construct some kind of overview embracing the ideas of Freud and the British analysts — such as Anna Freud, Melanie Klein, Michael Balint and Donald Winnicott — who had been active when he himself had been a student. His growing conviction that psychoanalysis is not so much concerned with the causes of human behaviour as with its meaning, and is better seen as one of the humanities than a science, does enable him to side-step many of the objections to psychoanalysis made by those such as Gellner and, as we shall see, Eysenck. However, nowhere in the 25 essays contained in this collection does he apply his mind to the issue which clearly troubles critics, namely the extent to which psychoanalysis is a self-fulfilling explanatory theory, whether it be of meaning or causes.

Meanwhile, there are others such as Professor Erdelyi, of the Department of Psychology at Brooklyn College, who struggle to salvage as much of Freud's expansive theory as modern insights in cognitive, physiological and neurological psychology will permit. Erdelyi's book uses case histories, laboratory studies, newspaper cuttings, visual art and poetry in an imaginative if occasionally wayward examination of Freudian theory. What emerges, however, suggests that what was lasting in Freud's conceptions is their general preoccupations. The specific elements of that gigantic canvas — the separation of mental functioning into id, ego, superego, theories of dream function and the nature of repression — just do not stand up to the relentless scrutiny of the laboratory scientists or the critical clinician. A particularly good example concerns Freud's pleasure principle. Freud assumed that pleasure/positive reinforcement resulted from tension-drive reduction; that, in short, pleasure was the cessation of pain — the so-called "Nirvana principle". The physiological facts suggest

otherwise. Pleasure and unpleasure appear to be not opposite sides of the same coin but two different coins altogether. More uncomfortable for psychoanalysts is the fact that the "pleasure" arising from stimulation of the pleasure centre in the brain is general in nature and *not* sexual as a great deal of psychoanalytical writing and excavation argues.

The most fundamental criticism of psychoanalysis, however, remains the same, 30 years on from when Hans Eysenck first mounted it. It is the fact that there is no convincing evidence that patients do better under analyses than they do under some other form of psychotherapy or psychiatric treatment. Such criticism does not come only from without. Anthony Storr, himself a Jungian analyst, has concluded that "the evidence that psychoanalysis cures anyone of anything is so shaky as to be practically non-existent". And Brian Farrell, a philosopher by no means hostile to analysis, has admitted that the impact of psychoanalysis

cannot be justified on the grounds that it contains a body of reasonably secure or established knowledge . . . it [is] only too painfully evident that analysis does not contain any such body of knowledge.

Characteristically, Eysenck puts the case with more exuberance and venom. At best, he concludes his devastating polemical assault, psychoanalysis is "a premature crystallization of spurious orthodoxies; at worst a pseudo-scientific doctrine that has done untold harm to psychology and psychiatry alike". The final verdict, however, is not in and it is doubtful that it will be within the lifetimes of the authors of these books. What does seem unarguable, however, is that in the one hundred years that have passed since Freud began to build his theoretical framework the theory still lacks any substantial validity and his school remains beleaguered. □

Scent of semi-science

Steve Blinkhorn

The Intelligence Men: Makers of the IQ Controversy. By Richard E. Fancher. W. W. Norton: 1985. Pp.269. \$17.95. £14.95

AT LAST, it seems, the soot and whitewash school of controversy has had its day. Here is a book about the IQ debate which is at once absorbing, informative, deftly written and, if the expression can be pardoned, a thundering good read.

The Intelligence Men is that rare inversion of the natural order of things: a first-rate book based on a second-rate notion. The notion, that one may discover why particular figures in the history of a debate took up their respective positions by examining their personal histories, is only as good as the sample of biographical material available and the accuracy with which it is interpreted; in any case, the standards of proof required of such a notion are far inferior to those proper to the debate itself. Fortunately analysis of this sort intrudes very little into Fancher's account of the lives and work of a dozen or so major contributors to the long-running dispute over IQ.

The delicious consequence of this plan has been a book reeking of the dubious scent of semi-science in the making. Where often a scientist is known to a wider public only as an author of published work, here that work is set in a personal context which illuminates and informs even when the technical level of the narrative is less than satisfactory. Pasteboard textbook characters have pasteboard theories to peddle. But the facts that Spearman registered for a PhD with Wundt (and took seven years to complete it), that Terman's introduction to psychology was a book on phrenology and that amongst Yerkes's motivations for seeking a career as a physician was the fact that it paid better than being a farmer, bring an unusual sparkle to academic history.

Kamin's brush with McCarthy's subcommittee on unAmerican activities; Jensen's origins as the son of a lumber and building-supplies dealer, and habit of conducting recorded symphonies at home with a chopstick for a baton; Binet as a child being forced by his father to touch a cadaver; Burt labouring to devise raw data to fit published statistics — none of this is relevant to the logic of scientific discovery. But, as Fancher suggests, the psychology of the scientist is at least as potent a force in determining the direction of theory. This, of course, is a view that can be taken to extremes. There was once a claim that Spearman, being British and therefore a monarchist, was driven to expect a single factor of intelligence, whereas Thurstone, being American and more democratically inclined, preferred a federalist view with several distinct abili-

Sigmund Freud — still dominant in the field of psychoanalysis.

On the track of Ice Age Mammals

A.J. Sutcliffe

This fascinating and extensive survey of the Ice Age, taken from a multi-disciplinary standpoint, will become a mine of information both for the research scientist and the layman. Fully illustrated throughout, featuring 5 double-page colour spreads commissioned from artist Peter Snowball. 224pp, 150 b/w illustrations + 5 double pages colour. 0 565 00869 2. Hbk. £12.95

Crows of the World, 2nd ed.

Derek Goodwin

An up-dated edition of this standard reference work on the familiar yet diverse crow family. Includes 3 new colour plates commissioned from Robert Gillmor. 300pp. approx. 6 colour plates. 1986. 0 565 00979 6. Hbk, approx. £30.00

The *Littoraria* species of Indo-Pacific mangrove forests.

D.G. Reid

A detailed study of 20 species of *Littorina scabra*, many previously unrecognised, with particular attention to the reproductive system by which the species can be reliably distinguished. A key to shells is also provided. 240pp, 99 illustrations, 1 colour plate. 0 565 00978 8. £35.00

A world list of mammalian species, 2nd ed.

G.B. Corbet & J.E. Hill

New edition of this easy-to-use reference book designed primarily for the non-specialist. Incorporates many additions and revisions since the first edition of 1980. 240pp. approx. 1986. 0 565 00988 5 £25.00

Publications Sales, British Museum, (Natural History), Cromwell Road, London SW7 5BD

ties ranking equally. Nothing so crude enters Fancher's book; rather, there is an elusive subtlety to the drift of the narrative that no review can hope to capture.

It is all the more unfortunate, then, that the last chapter reads like a hurried afterthought. In attempting to come to a balanced view of the current state of the debate, the author steps outside his role of historian and immediately becomes unconvincing. This is a pity, but a small blemish. As the origins of intelligence testing recede beyond living memory, this book does a real service by reminding us that present academic fisticuffs have their origins in an honest but often naive and blinkered struggle to make sense of human variability. No doubt future historians will judge present efforts to have been equally blinkered; but in what proportions are we now naive and honest?

Steve Blinkhorn is Director of the Psychometric Research Unit and Principal Lecturer in the Department of Psychology, Hatfield Polytechnic, PO Box 109, College Lane, Hatfield, Hertfordshire AL10 9AB, UK.

Go for Valhalla

Michael Spencer

The Joy of Science: Excellence and its Rewards. By Carl Sindermann. Plenum: 1985. Pp.259. \$16.95, £16.15.

SAMUEL Smiles, the Victorian author of such uplifting texts as *Self-Help* and *Men of Invention and Industry*, has been enjoying a revival of esteem on the New Right. Britain's Prime Minister has told unemployed teenagers to go out and start their own businesses, while one of her ministers has coined the immortal phrase "Get on yer Bike". We are urged to model ourselves on those who pursue success with relentless enterprise and determination.

Carl J. Sindermann is the Samuel Smiles of science, and has followed his earlier book *Winning the Games Scientists Play* with a further guide on How to Get On. His technique is modelled on that of Smiles: to examine in detail the upward climb of those who have achieved success. By "success" he means not the winning of Nobel prizes (a chimera that motivates more scientists than would ever admit it), but a job-satisfaction extending to administration and the manipulation of grant-giving bodies.

He cheerfully admits in his preface that the prospect of such a book did not endear him to his colleagues, who may have suspected that their own careers (thinly disguised under fictitious names) would be dissected for all to see. Undaunted, at late evening cocktail parties and professional meetings he pursued his chosen paragons long after their normal bedtimes, so as to analyse what made them tick.

The chapter on "The Ascendant Female Scientist" was, says the author, written against the strongly stated advice of all his female acquaintances, who were still smarting from a section entitled "Sex in the Laboratory" in his previous book. None of them, he says, would admit to the classification of "friend" after it was published.

Why, then he do it? The answer appears to be that Dr Sindermann is an old-fashioned scientific optimist who believes that all science is exciting and wonderful, and that anyone who succeeds in it is to be applauded and emulated. (In this he may have something in common with the august figure who once opined in print that it would be a pity for the world to blow itself up with nuclear weapons because that would halt the onward march of science.) Hardly anywhere in the book — whether discussing choice of research topic, career transitions or interactions with the outside world — does he discuss the problem of deciding whether a project is socially desirable. The word "ethics" does not appear in the index.

Dr Sindermann has little time for the also-rans, except as examples of where one can go wrong. He would certainly not agree with a friend of mine, who emerged limply from a two-hour session with a visiting celebrity to remark that the failures were much more interesting to talk to. He has harsh words to say about the Burnout, the Fade-out and the Guaranteed Loser. The latter category includes the Unwary Activist, who may (he says) damage his or her scientific credibility by espousing causes for social reform. The author classes such misguided people along with the Dilettante, the Hobbyist and the Chronic Underachiever.

Since most of us (by definition of that uncompromising word "excellence") are not going to reach Dr Sindermann's Valhalla of success, why should anyone read his book? The upwardly mobile graduate student with a taste for ruthless self-advancement will have his own ideas on how to make it. For those who have reached what the author calls the "midlife crisis" it is probably too late. The ageing scientist (to whom a chapter is devoted) is not going to believe a word of it.

Perhaps the most interesting thing about the book is what is missing from it. There is the same moral vacuum in the Royal Society's message to scientists, that they should learn how to manage the media in support of their chosen way of life. It is possible — just possible — that the current public mood of suspicion and alarm about the outcome of some scientific research is due not to inadequate public relations, but to a failure among scientists to think about the repercussions on ordinary people. Politicians have made the same mistake. □

Modularity of brain and mind

P.N. Johnson-Laird

The Social Brain: Discovering the Networks of the Mind. By Michael S. Gazzaniga. Basic Books:1985. Pp.240. \$17.95.
Neuronal Man: The Biology of Mind. By Jean-Pierre Changeux. Translated by Laurence Garey. Pantheon:1985. Pp.348. \$19.95.

THE brain is the organ of the mind. If you want to understand the mind, then you had better understand the brain. These two books, not perhaps as different as chalk and cheese, but certainly as different as brie and parmesan, share this philosophy. They both aim to elucidate the mind by establishing how the brain works. Michael Gazzaniga wants to demonstrate a link between the global organization of your brain and the way in which you come to believe in certain propositions — from prosaic assumptions about yourself to your propensity to hold religious beliefs. Jean-Pierre Changeux is a Gallic ghost-buster, who aims to rid you of your faith in the "ghost in the machine". He will explain your mind away: it is nothing but neurones, synapses, and electrical and chemical signals. His motto is *La Mettrie*'s: "The soul is merely a vain term of which we have no idea. Let us conclude boldly that man is a machine".

Gazzaniga is a distinguished neuropsychologist at the Cornell University Medical Center in New York, and is best known for his studies of the psychological consequences of the "split-brain" operation. His book is an intellectual autobiography that recounts the development of these studies, considers their implications and speculates about such larger issues as society, prehistory and religion. He writes in a loose, unbuttoned style, with numerous asides and anecdotes, and is at his strongest in describing his beautiful series of experiments on the effects of the split-brain operation.

If you fixate some point in the scene in front of you, then everything to the left of your fixation point is projected to the right half of your brain, and everything to the right of your fixation point is projected to the left half. Information is rapidly transferred from one half to the other by a massive bundle of nerve fibres, the corpus callosum. The split-brain operation is carried out to control extreme forms of epilepsy. The surgeon cuts the corpus callosum and its associated structures so as to isolate the left cerebral cortex from the right. The operation is highly beneficial in otherwise intractable cases, and, according to early results, had no effects on personality, mood or behaviour. However the absence of behavioural consequences did not square with some earlier studies on

animals carried out by Roger Sperry, and so Gazzaniga decided to check again. Under Sperry's supervision, he carried out the pioneering series of studies that revealed the operation's consequences.

The first effect he observed was the patients' inability to name anything that lies in the left visual field: such a stimulus projects to the right hemisphere, but the main language centres are located in the left hemisphere. Information can no longer be transmitted from one hemisphere to the other, and so the patients deny seeing the stimulus. However, when they are asked to make guesses about it, their emotional evaluations are almost identical to those they make when they can see it. They become frightened by terrifying pictures, though they still deny seeing them, and may attribute the cause

such distractions and thus scores higher on perceptual tasks.

When split-brain patients are given two matching tasks, one to solve in the left brain and the other to solve in the right brain, they readily perform them, but the verbal justifications they give for the responses made by the right brain are usually false even though the responses themselves are correct. Thus, if the command "walk" is flashed to the right brain, then the patient will indeed get up and start to walk. If asked why, the left brain, which is unaware of the command, readily concocts a confabulatory explanation. Here is the seed for Gazzaniga's principal hypothesis.

The brain is organized, he claims, into separate modules that can carry out various actions, maintain moods and per-

An early look at the raw material — structure of part of the brain from Julius Casserius *Tabulae anatomicae*, Frankfurt 1632. Book x, pl. iii.

of their fear to the demeanour of the experimenter.

If I remove the cooling fan from my micro-computer, the machine is soon incapable of carrying out any computations. Someone who knows little about computers might therefore infer that the fan plays a central role in computation. Analogous errors are an ever-present danger in the study of brain damage. Gazzaniga wisely resists them and repudiates the one-time vogue for alleged dichotomies between left-brain thinking (analytical and verbal) and right-brain thinking (intuitive and visual). His further studies have revealed some subtle phenomena. The right hemisphere typically can create better drawings than the left. Yet the right is not necessarily a superior visualizer: it does no better than the left in matching one readily nameable picture to another. Gazzaniga suggests that perhaps the right brain does not possess a special ability at perception. Instead, if the left brain has no immediate opportunity to exercise its linguistic ability, it may concentrate still more on the verbal aspects of the task — to the detriment of its perceptual performance — whereas the right hemisphere has no

ceive the world. They are independent units that work in parallel; and they contribute to what we are conscious of, but we are not aware of them. They can control behaviour, and so we sometimes do things for no reason that we are aware of — we act capriciously. The module that mediates language and consciousness, however, interprets our behaviour, and instantly contrives theories to explain it. That is why we think we have free will, and why we are likely to hold beliefs for which we have no objective evidence.

Another inherent danger in interpreting brain damage is to overlook the possibility that its effects are a result of compensatory changes. A sceptic might accordingly argue that Gazzaniga is right: one half of a split brain does contrive explanations for how the other half lives, but only because it has been forced to do so as a result of the operation. Normal people behave quite differently and are conscious of the roots of their behaviour. Of course, there is a long tradition in psychology — and considerable evidence — to the contrary. Likewise, the modular hypothesis has been independently postulated by a number of cognitive scientists in order to

make sense of the mechanisms of vision and language, the distributions of scores on different sorts of mental test, and other neurological disturbances. What is unique in Gazzaniga's account, however, is his emphasis on the confabulatory capacity of the interpretative module.

Knowledge of the brain has changed strikingly in the past 25 years. It used to be assumed that sensory information was conducted to the cortex, where there was an interchange with other information in the so-called "association" areas, and finally neuronal signals were transmitted to the motor areas responsible for the control of actions. This picture is now known to be a vast oversimplification. Jean-Pierre Changeux, who is a molecular neurobiologist at the Collège de France, has made important contributions to these developments in his work on neurotransmitters and the growth of neural networks. His prize-winning book was evidently a best-seller in France, and it is an outstanding attempt to convey to the general public an interdisciplinary understanding of the human nervous system.

Changeux begins with the tortuous history of concepts of the brain. He records the gradual recovery from Aristotle's original blunder in assuming that it functioned as a cooling device — a case of confusing the central processor with the fan — and describes the gradual ousting of the idea of "vital forces" by the modern electrochemical theory of the propagation of nerve impulses. The brain contains a dense interlacing of the dendritic webs of thousands of millions of neurones, through which pass myriads of electrical impulses, relayed across the synapses from one neurone to another by chemical transmitters or in some cases electrically. There are dozens of chemical substances that are now known to function as neurotransmitters, or as modifiers of their actions, including the nervous system's own internal pain-killers, the enkephalins and endorphins. The principles of the "wiring" of the nervous system are the same throughout the cortex, regardless of the functional specialization of a particular area. Nature seems to use the same basic building blocks over and over again, and employs no cells, circuitry or neurotransmitters unique to human beings. Organization determines function, and the modular principle extends downwards from regions of the brain that mediate

major functions to the cortical columns of neuronal structures. Changeux describes these discoveries with clarity and panache, making excursions into the brain chemistry of pain, thirst, rage and even orgasm.

Behaviour can be explained in terms of the mobilization of sets of nerve cells; their responses can be explained in physicochemical terms; and these interactions can be explained at the molecular level. But what about the subjective life of the mind, such as our ability to imagine a friend's face, our emotional experiences and our sense of self-awareness? Changeux's thesis is that mental states are identical to physical states of the brain. Percepts, images, concepts and all such "mental objects" correspond to the activity, electrical and chemical, of assemblies of neurones, dispersed through separate regions of the brain in the case of abstract ideas. Changeux admits that a given mental object may be constructed from slightly different neuronal populations, which may even differ in detail within the same individual from one moment to another. But he does not deal adequately with how the same mental state could arise from such different physical states of the brain.

The answer to this problem is to be found in a different species of materialism that can be traced back to Kenneth Craik and Alan Turing. What mentality depends on is not a particular physical substrate, but the functional organization of the processes that it makes possible. There is still no need to invoke mystical properties in explaining the mind, but this approach can be informed by the theory of computability. The brain is clearly very unlike an ordinary digital computer in the details of its construction and operation; yet it is arguably a computational device that is causally connected to the external world.

If one thinks of the brain as a system containing many processors that carry out computations in a parallel and distributed way, one can make sense both of Gazzaniga's modular hypothesis and of the relation between mentality and neurones — just as different algorithms can compute the same function, so the same mental state can arise from different configurations of neurones provided that the functional organization of their processes is the same. It is therefore necessary to understand what the mind's various computational tasks are, how they might best be carried out, and how such procedures can be neurally embodied. It is a pity that the work of Craik, Turing and the late David Marr, who did so much to clarify these issues, lies outside the scope of these two books. The brain is the organ of the mind, but the dependence cuts both ways. If you want to understand the brain, you had better understand the mind. □

Entropy parameters and quantum jumps

Walter Gratzer

Mayonnaise and the Origin of Life: Thoughts of Minds and Molecules. By Harold J. Morowitz. Charles Scribner's Sons: 1985. Pp.256. \$15.95.

Natural Acts: A Sidelong View of Science and Nature. By David Quammen. Lyons Books (Schocken): 1985. Pp.221. \$16.95.

THE first of Dr Morowitz's essays finds him on the Galapagos Islands, the third in an aeroplane approaching New Delhi and not long after we meet him pacing the deck of a cruise boat on Glacier Bay in Alaska. Where other orbiting professors sort their slides or touch up the odd grant application, Dr. Morowitz, it seems, reaches for his pen and kicks his muse into action.

As a popularizer of science Morowitz is by no means in the Haldane class, but, at his best, as when he is ruminating on the quirks of scientists, dead and alive, and the assaults on science by the Great Unwashed, he is distinctly good company. He writes captivatingly on the eccentric palaeontologist, John Bell Hatcher, and on the unhappy Philip Gosse, a Victorian worthy, who as a Plymouth Brother, a zoologist and FRS, and friend of Darwin, was tormented by the geological and palaeontological evidence against Bishop Ussher's chronology and by such teasers as whether the occupants of the Garden of Eden possessed navels. (Such matters were far more satisfyingly resolved by the mediaeval schoolmen: what could be more pleasing, for example, than the logic of Origen, who held that since the sphere was the most perfect of all shapes by virtue of the invariant distance between its centre and all points on the surface, we would all on the Day of Judgement be transformed into spheres and roll into paradise.) Morowitz respects men such as Gosse for their tortured honesty of intellect. He deals sharply, by contrast, with those modern fleas on the body of science, the creationists and parapsychologists. One of his most entertaining pieces is a magisterial analysis of the thermodynamics of ESP.

I am less sure about a stertorous attempt to rehabilitate Teilhard de Chardin. But then again Morowitz comes up trumps on popular perceptions of entropy, which seems to have joined parameter, extrapolate and quantum-jump in the journalistic vocabulary. Here is a political pundit, quoted by Morowitz: "Entropy helps to explain why we have runaway inflation, soaring unemployment, bloated bureaucracies, a widely escalating energy crisis and worsening pollution". Poor Boltzmann (over whose remains in Vienna is hewn in stone the inscription

NEW! FROM ELSEVIER

GEOLOGY IN PETROLEUM PRODUCTION

A.J. Dijkers, The Hague, The Netherlands

(Developments in Petroleum Science, 20)

A practical book for geologists involved in the production of petroleum, here is a comprehensive review of basic techniques in production geology, the links with related subjects, and the function of geologists in the planning and operation of all phases of oilfield development. The first part discusses the basic techniques used in the analysis and graphic representation of the stratigraphy, tectonic structure, reservoir sedimentology and hydrocarbon distribution of an oilfield. The second part describes how this knowledge is applied in the various phases of field development (appraisal, development, drilling, supplemental recovery, reserve estimating, unitization). The mutual support between production geology and neighbouring disciplines such as seismology, log interpretation, reservoir engineering is stressed.

Throughout the book, the text is secondary to the illustrations; these are examples, mostly hypothetical, of conditions and techniques discussed, designed so as to bring out as clearly as possible the importance of the points made. It is thus an ideal book for graduate students, specializing in petroleum geology and for participants in post-graduate courses, in universities or within industry, and will undoubtedly provide the reader with a sound basic knowledge which will allow him to make an effective contribution to the application of geology in petroleum production.

COUPLED OCEAN-ATMOSPHERE MODELS

Proceedings of the 16th International Liège Colloquium on Ocean Hydrodynamics, Liège, May 7-11, 1984

J.C.J. Nihoul, Liège University, Belgium (editor)

(Elsevier Oceanography Series, 40)

The exchange of momentum, heat, moisture, gases (such as CO₂ and O₂) and salt between the atmosphere and the ocean is a phenomenon of paramount importance for the dynamics of the atmosphere and the ocean. With the pressing need for reliable climate forecast (e.g. to deal with severe food and energy problems) interactive ocean-atmosphere models have become one of the main objectives of geophysical fluid dynamics.

This, the latest proceedings of the famous International Liège Colloquia on Ocean Hydrodynamics, provides the first state-of-the-art review of interactive ocean-atmosphere modelling and its application to climates. The papers are by active and eminent scientists from different countries and different disciplines. Together, they provide an up-to-date survey of major recent discoveries and valuable recommendations for future research.

CLAY MINERALS

A Physico-Chemical Explanation of Their Occurrence

B. Velde, E.N.S., Laboratoire de Géologie, Paris, France

(Developments in Sedimentology, 40)

This book follows another by the same author — *Clays and Clay Minerals in Natural and Synthetic Systems* (1977) — which the author considered as "a first attempt to put some order in the house of clay petrology." It was described as "an excellent first attack on clay mineral petrology... informative, and stimulating because of the method of presentation and the open-door treatment of the subject." (*Earth Science Reviews*). This new book describes clay mineral occurrence in terms of the physical and chemical forces which influence it. It includes a geological description of mineral occurrence, a definition of the major features of clay mineral composition, and an indication of the physical-chemical boundaries of these occurrences. The book also presents general patterns for the geological environments of weathering, sedimentation, burial diagenesis, deep sea basalt alteration, hydrothermal alteration of acidic rocks and chemical precipitation in acidic and basic environments (magnesium, silicate and zeolite systems). The major clay groups are related to one another as they occur in geological systems through the use of graphical analysis.

The author has thoroughly reviewed the relevant literature for the last 25 years. The data and analyses obtained and presented in this book will not only make interesting reading, but will also prove extremely useful to those involved with studies in deep sea research, mining geology, petroleum geology, agronomy and civil engineering.

Astrophysics of Active Galaxies and Quasi-Stellar Objects

Edited by Joseph S. Miller

This volume is based on the 1984 University of California, Santa Cruz Astrophysics Workshop on the subject 'Astrophysics of Quasars and Active Galactic Nuclei'.

0 19 855717 5, 450 pp., illus., OUP/University Science Books £37

Industrial Numerical Analysis

Edited by Charles Elliott and Sean McKee

This book results from the work of the Oxford Study Groups with Industry (OSGI) and the University Consortium for Industrial Numerical Analysis (UNINA).

0 19 853190 7, 270 pp., illus., Clarendon Press £20

The Ecology of Woodland Rodents

Bank Voles and Wood mice

Edited by J. R. Flowerdew, J. Gurnell, and J. H. W. Gipps

Fourteen papers review the ecology of the three rodent species commonly found in woodland throughout Britain and Europe.

0 19 854003 5, 500 pp., illus., Clarendon Press £35
Symposia of the Zoological Society of London No. 55

Advances in Animal Conservation

Edited by J. P. Hearn and J. K. Hodges

These papers outline the scientific advances which have been made to assist in the preservation of exotic species in captivity and in the wild.

0 19 854002 7, 250 pp., illus., Clarendon Press £35
Symposia of the Zoological Society of London No. 54

Metamorphosis

Edited by Michael Balls and Mary Bownes

The proceedings of a symposium held at the University of Nottingham in 1983 which aimed to take an up-to-date, research-oriented look at the significance and control of metamorphosis, with particular emphasis on insects and amphibians.

0 19 857183 6, 448 pp., illus., Clarendon Press £45

Springer's Autumn Collection

Microsurgical Models in Rats for Transplantation Research

Editors: A. Thiede, E. Deltz, R. Engemann, H. Hamelmann, University of Kiel

1985. 145 figures, 76 tables. XIX, 392 pages. Hard cover DM 198,- ISBN 3-540-13221-X

Several international research groups have contributed their work and experience to the compilation of this comprehensive survey of microsurgical models of organ transplantation in the rat. It demonstrates operative techniques of all types in detail and gives the results of immunological and morphological analyses of rat organ transplantations. Not only a wide range of organs possible for operations, but also a variety of experimental models for the analysis of problems arising from organ transplantations are presented.

Glucocorticoid Hormone

Mechanisms of Action

Editors: Y. Sakamoto, F. Isohashi, Osaka University

1985. Approx. 230 pages. Hard cover DM 69,- ISBN 3-540-15583-X Distribution rights for Japan: Japan Scientific Societies Press, Tokyo

This book covers the latest advances in glucocorticoid hormone receptors and the molecular mechanisms by which these hormones exert specific effects in target tissues. The underlying physiological process is divided into three steps: a steroid-binding step, an activation or transformation step, and a translocation step, and the first chapters in this book are arranged accordingly. Later chapters are devoted to recent developments in other steroid receptor systems and the mechanisms of glucocorticoid resistance. Each chapter is an invited contribution by an internationally recognized scientist and includes previously unpublished results as well as up-to-date references.

First Trimester Fetal Diagnosis

An International Symposium

Convento delle Clarisse, Rapallo, Italy. October 25-27, 1984

Editors: M. Fraccaro, Pavia; G. Simoni, B. Brambati, Milano

1985. 133 figures. IX, 355 pages. Hard cover DM 168,- ISBN 3-540-15785-9

This is a new and comprehensive study of all aspects of first trimester fetal diagnosis of genetical diseases. It describes new obstetrics, cytogenic, biochemical and molecular methods based on the use of chorionic villi sampling, and the pioneers and initiators of these methods discuss the different approaches to trophoblast. The book also reports on direct and culture methods for chromosome preparations, biochemical experiments, DNA studies and fetal pathology, and offers an evaluation of the diagnostic results and risks so far discovered worldwide.

U.F. Westphal, Annapolis

Steroid-Protein Interactions II

1985. 80 figures, 153 tables. Approx. 620 pages. (Monographs on Endocrinology, Volume 27). Hard cover DM 320,- ISBN 3-540-15321-7

Since volume I of the monograph was published in 1971, significant developments in the study of steroids have demanded a completely new edition. This book is both a supplement and continuation, following up previous discussions and shedding new light on steroid interaction with serum albumin and α_1 -acid glycoprotein. It greatly expands on topics of anti-steroid antibodies and steroid transforming enzymes, and reports mainly on progress in corticosteroid-binding globulin (CBG), progesterone-binding globulin (PBG), and sex steroid-binding protein (SBP).

Peptide Hormones in Lung-Cancer

Editors: K. Havemann, Marburg; G. Sorenson, Hanover, NH; C. Gropp, Wuppertal

1985. 100 figures, 63 tables. XII, 248 pages. (Recent Results in Cancer Research, Volume 99). Hard cover DM 138,- ISBN 3-540-15504-X

Contents: Hormones and Neurotransmitters in Normal Lung. - Biochemistry of Peptide Hormones and Neurotransmitters Produced by Lung Cancer. - The Endocrine Lung Tumor Cell: In Vitro Studies. - The Endocrine Lung Tumor Cell: Morphological Aspects. - Clinical Implications of Peptide Hormone Production in Lung Cancer. - General Aspects of Tumor Growth. - Subject Index.

Tumor Aneuploidy

Editors: T. Büchner, C.D. Bloomfield, W. Hiddemann, D.K. Hossfeld, J. Schumann

1985. 49 figures, 56 tables, 152 pages. Soft cover DM 48,- ISBN 3-540-15376-4

From the preface: "The contributions collected in this book cover several major aspects of present knowledge concerning the occurrence and clinical significance of chromosome abnormalities as delineated by karyotype analyses or measurements of the cellular DNA content. Updated results and surveys are contributed by authors from 8 centers in Europe and in the United States. As a result of their cooperation this volume presents an overview of the current status of cytogenetics in human malignancies with particular emphasis on their clinical relevance."

P.L. Ballard, University of California, San Francisco

Hormones and Lung Maturation

With a contribution by R.A. Ballard

1985. 85 figures, 80 tables. Approx. 370 pages. (Monographs on Endocrinology, Volume 28). Hard cover DM 198,- ISBN 3-540-15320-9

Contents: Lung Development. - Glucocorticoid Effects in Vivo. - Glucocorticoid Receptor. - Role of Endogenous Corticosteroids. - Antenatal Glucocorticoid Therapy: Clinical Effects. - Antenatal Glucocorticoid Therapy: Hormone Concentrations. - Thyroid Hormones: Effects and Binding. - Beta-Adrenergic Agonists. - Other Hormones. - Hormone Interactions.

Springer

Reader Service No.46

$S=k \log \Omega$) surely did not foresee this.

Morowitz offers some agreeable literary diversions and his thermodynamite's view of the passage in *Ulysses*, in which Leopold Bloom boils a kettle for his shaving water, deserves to be preserved. He is also rather good on dentists; he enjoys the "intellectual and aesthetic pleasure" of feeling a craftsman at work in his mouth. (Bernard Shaw took the same view: there was nothing more soothing, he wrote in one of his music criticisms, after a harrowing series of recitals, than to have one's teeth drilled by a finely-skilled hand.) There is much in this collection to entertain, sometimes to annoy and only occasionally to bore.

David Quammen disarmingly confesses to being a dilettante rather than a scientist, "a haunter of libraries and a snooper". He writes natural history in an unmistakably American style and is given to apostrophizing his reader in sporting metaphors. "Truly", he says, speaking of the larger kind of sea cucumber, "these guys are out in left field". This, I own, stretches my tenuous grasp of baseball. And what, for that matter, is this Hostess Twinkie, that a seal allegedly resembles in section?

The sea cucumber opens Quammen's collection, and its trials are considerable: the tiny parasitic *candiru* fish, for instance, enters and leaves the cucumber with impunity by way of the nether passage, lingering only to feed on its vitals. "You'd think", Quammen exclaims, "the little bugger was selling encyclopaedias". Well, these are not the lapidary periods of a Medawar or Gould; but we do learn how the resourceful cucumbers deal with the situation when they eventually weary of the tiresome intruder: they evert themselves and "blast their own gut and internal organs out through their own anus". Humans are denied this recourse, and, says Quammen, when the *candiru* enters the urethra it lodges there, its spines facing backwards, and the only alternative to death by blood poisoning is amputation. Beginning to feel faint, I passed on to the next story, which is about bats, and here was rewarded by an account of a scheme by the American military during the Second World War to subdue the Japanese by dropping bats, each fitted with a napalm bomb and a little parachute, on their cities.

Quammen's book is full of strange information about animals and their habitat, about Tycho Brahe's artificial nose, and other such oddities. His exuberance carries one, sometimes unwillingly, along. He has a penchant for the poetry of Donne, and an informed concern for wildlife and the environment that is altogether heartening; his book deserves every success. □

Behind the scenes in the fight on tropical diseases

Adetokunbo O. Lucas

From the Face of the Earth*. By June Goodfield. André Deutsch: 1985. Pp. 256. £10.95.

THE public exhibit an insatiable hunger for news about medicine and the medical sciences. In this book June Goodfield provides a five-course offering to feed the layman's appetite for "stories of medical achievement". As popular science, it translates into everyday language scientific information that is often obscured by jargon. The story telling is enlivened by taking the reader behind the scenes of scientific events — we read not only of dedication and the determination to succeed, but of personal disputes, divorce, dementia and other such human problems.

The first story about Kuru contains all the excitement of a strange disease, uniformly fatal among the sufferers, with a maximal impact on women and children and threatening to wipe out a whole community. This account highlights the role of those who finally solved the mystery. At the top of the list is Carleton Gajdusek, the deserved winner of a Nobel prize for identifying the cause of Kuru and for the discovery of slow viruses as causes of human disease. June Goodfield, however, notes but does not stress the point that control of Kuru in Papua New Guinea did not result directly from the outstanding biomedical and behavioural research which she so vividly describes. Rather, the decline in the incidence of Kuru apparently stemmed from action taken by some person(s) unnamed, who, in the 1950s, forced a cultural change in the ritual method of disposing of the dead. Who,

one wonders, were these faceless persons? What was their motive? Was it mere abhorrence of a strange cultural practice, or did they somehow intuitively sense that such practices could have fatal consequences?

The Kuru story illustrates the fall-out effect by which research on a specific problem can generate new knowledge of fundamental importance and unexpected benefit in other areas. Thus the work in Papua New Guinea has brought to Europe and North America new insights to diseases of local interest, such as Gerstmann-Straussler Syndrome and Creutzfeldt-Jakob Disease.

Discipline, dedication and imaginative resourcefulness are the main ingredients of the next story on hepatitis B vaccine. Illustrated here is the point that the identification of the appropriate risk groups is an essential stock-in-trade of the epidemiologist, from classical studies on scurvy among English sailors, to research into cancer of the lung among smokers.

"The Three Valleys of St Lucia" deals with a large operational research programme aimed at comparing strategies for the control of schistosomiasis. Unlike Kuru, a unique disease in an island population, schistosomiasis is widespread in the tropics, affecting some 200 million people. It is not new — its eggs have been found in an Egyptian mummy — but it presents a fresh challenge where projects such as irrigation schemes and man-made lakes result in expansion of the population of the vector snails, an increase in man-water contacts, and thus intensification and broadening of the distribution of the disease.

The St Lucia story well illustrates the practical questions that need to be answered in translating theoretical options into effective strategies. And, again, the research provided answers that were useful not only on St Lucia but also in other areas. Recently, the World Health Organization proposed new strategies for the control of schistosomiasis which owe much to the findings at St Lucia, updated to take note of recent advances in technol-

*In the United States *Quest for the Killers*, published by Birkhäuser price \$24.95.

Schistosome sporocysts in the head-foot region of a snail. From *Schistosomiasis: The St Lucia Project* by Peter Jordan. Cambridge University Press. To be reviewed in *Nature*

ogy, in particular the availability of a new, well-tolerated drug.

The chapter on leprosy is interesting, but perhaps premature in comparison with the other stories. It tells of the search for a vaccine; but while much progress has been made over the past decade we are still far from finding a vaccine of proven efficacy for operational use.

The last story, on the fight against smallpox, provides a grand finale in that it fully justifies the title of the British edition of the book. This was a unique achievement, the total eradication of a disease that presented a worldwide challenge. Even though Kuru may disappear, one cannot sign its death certificate with the same confidence as was done for smallpox on 8 May 1980 at the World Health Assembly in Geneva. Although there has been some speculation about the feasibility of completely eradicating other infections "from the face of the Earth" — proposed candidates include measles and poliomyelitis — no other disease presents the combination of features which made possible the difficult task of eradicating smallpox.

Most of the data required for epidemiological surveillance of smallpox could be obtained from fairly simple clinical observations of sick patients, and the examination of scars of healed natural infections or vaccination scars. Laboratory help was required in the identification of the small proportion of atypical cases, and for the differentiation of smallpox from other pox diseases. Most other infections present more formidable problems; the clinical features are usually not sufficiently characteristic to permit differential diagnosis on simple clinical examination, and there are usually no pathognomonic scars to identify those who have had previous infections or are protected by immunization.

Apart from satisfying the demand for exciting accounts of medical discoveries, this book and similar ones draw the public into the debate about investment in the biomedical sciences. On the one hand, at times of economic recession, reduction in the budgets for biomedical research often seems a soft option because the venture does not command a powerful constituency. On the other hand, when threatened by the appearance of such problems as Legionnaire's disease and AIDS, people are anxious to know that something is being done to control the scourge. This book shows that breakthroughs do not leap out on the order of clever scientists. It portrays the path to knowledge as a difficult one, more often crossed by disappointments than by the discoveries that come as the final reward for long-sustained devotion to science and the improvement of human health. □

Adetokunbo O. Lucas is Director of the Special Programme for Research and Training in Tropical Diseases, World Health Organization, 1211 Geneva 27, Switzerland.

Lemons and limes

Joe Collier

Drug Discovery: The Evolution of Modern Medicines. By Walter Sneader. Wiley: 1985. Pp.392. Pbk £12.95, \$21.95.

PHARMACOLOGISTS, physicians and legislators alike are now very wary of assuming that a drug is necessarily a medicine. Whereas a drug is any chemical substance that modifies a biological process, a medicine is that rare drug that can be used in patients to treat disease.

It is this distinction that occupies regulatory authorities (such as the Committee on Safety of Medicines, and the Food and Drug Administration) when licensing drugs for medical use; equally, it is the gap that the pharmaceutical industry strives to bridge so that new products can be marketed. Accordingly, as advances in fields such as biochemistry, genetics, immunology and pharmacology have led to the production of evermore sophisticated drugs, legislators have demanded increasingly detailed information about them before they will consider granting a licence. This balance now dominates the development of new therapeutic agents, and it is to this end that industry labours to discover how new drugs are absorbed, metabolized and excreted, how they should be formulated to be delivered to best advantage, how the dosage frequency should be adjusted to offer the greatest chance of efficacy, and, in longer term trials, the details of safety and efficacy.

Walter Sneader seems to be almost oblivious of these issues which are so central to the title of his book. They neither seem to be a consideration from which he might view the past, nor have they proved worthy of mention as a topic in their own right (and one so admirably dealt with by R.D. Mann in *Modern Drug Use: An Enquiry on Historical Principles*, published last year by MTP Press).

Instead, Sneader has filled the book with classical information. Each chapter (there are 16 in all) is devoted to a single broad therapeutic category, such as antibiotics, cardiovascular drugs, psychopharmacological agents, and in each the group is traced from the earliest reference to a seminal substance (penicillin, digoxin, Rauwolfia) through to drugs developed in recent history (the date seems to depend on Sneader's interests; inotropic agents stop with digoxin in 1933). The material is mostly in story form, in which the full names and addresses of each and every worker are listed, as are the movements of compounds and ideas between departments, companies and continents. There is an abundance of anecdotal information, clearly written and easy to follow — it is fascinating, for instance, to learn that scurvy returned as a threat to sailors when the trusty lemon juice was replaced by lime; lime juice, which was introduced for reasons of economy, has, we are told, about one-quarter of the ascorbic activity of lemon juice.

Two good reasons for publishing a new history book are that either it reveals fresh information or it analyses history from a

Eighteenth-century manufactory of drugs, with a direct sales outlet to the public (far right). The illustration appears in *The Development of a Medicine*, by R.B. Smith, recently published by Macmillan, London (hbk £30; pbk £12.95)/Stockton, New York (hbk \$60).

● Without fuss or pretension Smith's short book (160 pages) describes the development of medicines from their discovery (by serendipity or search), through their manufacture, their assessment both in the laboratory and the clinic, and on to the procedures involved in their marketing as licensed products. It gives a simple and straightforward account of contemporary practice in Britain, written by someone obviously familiar with the industry — when discussing drug company activity the book gives some rare glimpses of commercial philosophy in the pharmaceutical business. The book suffers from apparently being compiled in a hurry (tables illegible, legends wanting) but these should be corrected for the second edition that will surely come.

Joe Collier

novel point of view. Unfortunately, *Drug Discovery* does neither. The author's statements are always left open to question because no references are given in the text, so leaving the reader to search the rather poor and imprecise chapter bibliography at the end of the book. Interestingly, this sacrifice was made so that the text, which was written to convey "drama and excitement", should not be disrupted. However without references to contemporary information, the book has lost much scientific credibility.

Perhaps more annoying, there seems to be no benefit of hindsight. The ethical issues that have emerged so forcefully over the past 30 years and now engulf medicine seem to have left no impression. For its easy pace and the stories it relates I would expect the book to have its devotees; but as a serious historical account it falls short of what should be expected. □

Joe Collier is Senior Lecturer and Honorary Consultant in Clinical Pharmacology at St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE, UK.

A stir in the primeval soup

Jacques Ninio

Seven Clues to the Origin of Life: A Scientific Detective Story. By A.G. Cairns-Smith. Cambridge University Press:1985. Pp.123. £9.95, \$17.95.

WE ALL admire the high technology feats that the simplest cells achieve in duplicating chromosomes, translating genes into proteins and adjusting their enzyme activities to their immediate needs. All such pathways are interdependent, each relying on all the others, as in an arch that would collapse if any one of its stones were missing. How did the first cells arise, if life requires, at a minimum, a translation apparatus to make proteins to replicate DNA?

The usual answer is that some 4×10^9 yr ago the Earth was a gigantic organic reactor producing masses of small molecules, amongst which were amino acids, sugars and nucleotides. Spontaneous polymerizations occurred, leading to nucleic acids that could replicate without the help of enzymes. Some of these "naked genes" acquired control over their environment. The coupling between nucleic acid replication and peptide synthesis became tighter and tighter until it became a strict coding relationship.

Cairns-Smith objects to this view; he believes that primitive organic reactors were more likely to produce tars and sludges than fine biochemical products, and that nucleotides are complex molecules that require sophisticated mechanisms for their production. Also, if a low-technology machine is to work, it must avoid the mutual dependency of its parts that is characteristic of more complicated machines. But, he says, the very existence of a primitive life-form made the synthesis of well-defined organic molecules possible. Amongst these, fancy polysaccharides, with no genetic use, might initially have been precursors of DNA or RNA. According to Cairns-Smith, new genes and the machineries they controlled gradually took over from the older forms of life: "None of the fibres in a rope has to stretch from one end to the other . . . new 'gene fibres' may be added and others subtracted without breaking the overall continuity".

These ideas are well known among scientists in general but are rarely discussed openly. In the origins-of-life research community, people seek a comfortable corner where they are least likely to interact with competitors. Yet, consider the fundamental issue: is nucleic acid replication conceivable in a prebiotic world? We are flooded with so-called theoretical treatments which generate models of the evolution of prebiotic self-replicating nuc-

Marking the path

Peter Laing

The Biotechnology Business: A Strategic Analysis. By Peter Daly. Frances Pinter, London/Rowman & Allanheld, Totowa, New Jersey:1985. Pp.155. £16.50, \$25.

THE emergence of an international industry based on molecular biology and immunology is a striking example of the potential economic benefits of government funding of basic research. Equally, however, the commercialization of biotechnology well-illustrates the familiar pattern of technological innovation being avidly and rapidly exploited in the United States and only belatedly in Europe.

In the United States, the availability of venture capital and an entrepreneurial business climate have led to the formation of numerous specialist biotechnology companies. These have been able to attract many of the brightest academic scientists (who would not normally have considered an industrial career) and concentrate upon the problems of developing marketable products. The large, established American companies, aware of the many studies that have shown that technical innovation most often stems from small, flexible and highly-specialized firms, have generally encouraged this process by the provision of research contracts (and even equity finance) for start-up companies, obtaining in exchange the commercial rights to future products.

By contrast, in Europe the start-up company as an engine of technological change has until very recently been a rarity. The brunt of commercialization of new technology has been borne largely by the established industrial companies, in which new ideas have a depressing tendency to be stifled or restrained by corporate inertia and the "Not Invented Here" syndrome. This situation has been compounded by a general lack of contact between industry and academia, particularly in the biological sciences, with the result that the more enterprising scientists have either remained in universities or left for North America.

In Japan, a strong sense of national purpose and a cultural preference for con-

sensus solutions have engendered active cooperation between Government, industry and academia with the aim of establishing national priorities for the exploitation of new ideas and identifying the means of bringing them about. Even so, the vehicle for commercialization in Japan has invariably been the established company — indeed, companies in moribund or declining industries have often been selected for revitalization by the injection of funds for biotechnology projects.

The Biotechnology Business is a comprehensive and readable guidebook to the commercial side of the biotechnology industry. As acknowledged by the author, it leans heavily on the excellent Office of Technology Assessment report *Commercial Biotechnology*, published in 1984, but is less nationalistic in its approach (and also weighs only a quarter of the OTA report's daunting 1.2kg).

Daly's emphasis on strategic analysis, made explicit in his sub-title, has resulted in many interesting case studies. Among them is a timely comment on the American company Genex, warning of the dangers of the company's heavy reliance on a single manufacturing contract for L-phenylalanine with G.D. Searle. This contract was terminated a few weeks after the book was published, plunging Genex into a financial crisis.

The source material for the book appears to have been culled largely from articles in specialist biotechnology magazines. These have tended to concentrate on the newsworthy start-up companies, and there is in consequence an under-representation of the strategies which are being adopted by the large chemical and pharmaceutical firms; now that the basic technology is more widely disseminated, such companies are beginning to make real inroads into the market. The likely impact of these moves on the start-up companies suggests not only a volatile employment market for the scientists involved, but, as Peter Daly points out, the development of an even more fruitful area for strategic analysis than the biotechnology industry has provided to date. □

Peter Laing is an Assistant Director of N.M. Rothschild Asset Management Ltd, New Court, St Swithin's Lane, London EC4P 4DU, UK, which acts as investment adviser to Biotechnology Investments Ltd.

leic acid populations as though the very existence of such reactions were not the primary theoretical issue. With highly-skilled organic syntheses, the beginnings of something like non-enzymatic DNA or RNA replication are observed. But now, as Schwartz and Orgel have said (*Science* 228, 585-587; 1985), we need to "design reactions that proceed efficiently with more plausibly prebiotic substrate mixtures". Sooner or later, organic polymers, able to replicate in the laboratory and having simpler backbones than DNA or RNA, will be synthesized. Then the idea of "takeover", as Cairns-Smith has called it, will become inevitable.

Cairns-Smith, however, is far more radical than this, in that he rejects the concept of any primitive *organic* gene. Instead, he thinks in terms of clay particles, made of successive layers, each new layer added on top reproducing the defect structure of the previous layer; or of clays made of a succession of various kinds of uniform layers, that grow sideways. If such particles break across the layers, then the one-dimensional information contained in the particular succession of layers is conserved. Ways in which clays might influence organic reactions and use them for their growth are discussed in this book. Thus clay particles are suitable substrates for natural selection. Will field studies be conducted on the population structure of clay particles in given ecological niches? Or will some courageous young scientist design a clay-chemostat where the growth of clay crystals will be studied under various selective pressures?

Cairns-Smith's ideas deserve to be

assimilated and discussed. In *Seven Clues to the Origins of Life*, a layman's version of his earlier book *Genetic Takeover*, all his essential theses are presented in a clear, precise and condensed manner. The choice of a deductive form of presentation for his arguments (clays are introduced only three chapters from the end), buttressed by references to Sherlock Holmes, lends much rigour to the plot, and leaves no escape exit. How can low-technology life be designed, and how can it evolve towards the high-technology form? I know of no other book that succeeds as well as this one in maintaining this central question in focus throughout. It is a summary of the best evolutionary thinking as applied to the origins of life in which the important issues are addressed pertinently, economically and with a happy recourse to creative analogies.

The concept of "takeover" is an important evolutionary one, and may apply to a wide variety of situations. I regret in this respect that the author did not attempt to analyse concrete biological examples (such as the origin of split genes, RNA catalysts and ribosomes, or the design of the immune system) in the light of this idea. Inevitably, I think, schemes in which things acquire complexity of detail without a change in their organization will have to compete with "takeover" schemes. The time has now come for those scientists working on the subject of the origin of life to cease dealing with such ideas obliquely. □

Jacques Ninio is at the Institut Jacques Monod, Tour 43, 2 Place Jussieu, 75251 Paris Cedex 05, France.

that may occur in any population of individuals". He transferred this anti-essentialism from entomology to human behaviour. Human sexual behaviour cannot be pigeon-holed; just as the world of wasps was a continuum in each and every one of its aspects, so too the male population cannot be divided into two discrete groups, heterosexual and homosexual.

The enigmatic smile of a swan — or an upside-down flamingo?

Gould teases out the wider implications of a particular scientific enquiry, from the taxonomy of wasps to a more accurate — and tolerant — understanding of what is regarded as sexual deviation. The scientific, moral and political (Kinsey had the misfortune to coincide with Senator McCarthy) implications are shown to interact.

The essays range widely from speculation about the reason for the extinction of the dinosaurs to the bizarre and unhappy cases of the Hottentot Venus and of Ritta-Christina, the celebrated siamese twin sisters. The style is relaxed but not flip; the content all the better for being disciplined by the limits of the monthly column. If there is a weakness it is Gould's rather too obvious wish to hook his reader with a startling opening paragraph. An essay on continuity and quirkiness in evolution leads off with Michelangelo and one on the flamingo's eating habits with Buffalo Bill. It is good journalism but unnecessary: in all these essays the subject matter is compelling enough in itself.

Scientists who communicate their enthusiasm to a wider audience are regarded by some of their professional colleagues as vulgar; if it can be explained to a layman it cannot be serious. Gould brushes aside that mixture of arrogance and insecurity. His essays popularize science in the same sense that Macaulay popularized history — by making it interesting and entertaining to read. Roll on volume five. Meanwhile I shall be looking for copies of volumes one to three. □

Appeal to the laity

John Rae

The Flamingo's Smile: Reflections in Natural History. By Stephen Jay Gould. W. W. Norton: 1985. Pp. 476. \$17.95. To be published in Britain in February 1986, £12.95.

It is 20 years since C. P. Snow described the gulf fixed between scientists and non-scientists in academia. Not much has changed. The two communities continue to go about their business like a couple of Englishmen travelling in a foreign land: they are on the same journey but have nothing to say to one another because they have never been introduced. The non-scientist complains that the scientist cannot communicate what he is doing in a language that the layman can understand. The scientist complains that the non-scientist defines language in narrowly non-scientific terms — why should a biologist have to explain what he means by morphology any more than a grammarian has to explain what he means by tautology? No doubt it is the education systems

that are to blame; meanwhile the dialogue of the deaf continues.

Stephen Jay Gould overcomes this problem, not by laicizing the language, but by using it in the context of intellectual enquiries that any intelligent person can understand and by a technique of cross-referencing that relates the scientific enquiry to comparable problems in other disciplines. It might be argued that as a palaeontologist and evolutionary biologist he has an easier task than say, the nuclear physicist. But easy or not he succeeds brilliantly. This collection of essays, the fourth to be based on his monthly column in the *Natural History Magazine*, communicates both the fascination and the universality of scientific study in a way that can hardly fail to intrigue scientist and non-scientist alike.

Take, for example, Kinsey and the wasps. Kinsey's reports on sexual behaviour were not the product of his desire to promote sexual enlightenment. He drifted into sex research by accident and applied to the question his experience as America's leading taxonomist of wasps. His study of wasps persuaded him — in his own words — "of the uniqueness of individuals and of the wide range of variation

Biology and the behaviour of man

John Maynard Smith

Vaulting Ambition: Sociobiology and the Quest for Human Nature.

By Philip Kitcher.

MIT Press: 1985. Pp. 447. \$24.95, £24.95.

Do we really need another critique of sociobiology? In general, probably not, but perhaps we need this one. Kitcher, like everyone else, approaches the problem with prejudices, but he tries harder and more successfully than most to rise above them. Prejudices are inevitable. It is natural for geneticists and evolutionary biologists to hope that their disciplines will throw new light on the human condition, and equally natural for social scientists to resist the threatened takeover. More important for many of us, previous efforts to apply biology to human affairs have too often ended up as justifications for racial, sexual and class inequalities. Kitcher, who grew up in England, has not forgotten that, in the post-War years, schoolchildren were divided at the age of eleven into sheep and goats, and that this division was justified by the leading experimental psychologists of the day. He and I share this experience — he as a tested child and I as a parent of tested children. It has left us cautious about proposals to use biological theory to plan human institutions.

Kitcher, then, is unsympathetic to the claim that evolutionary biology can guide

... what we now need in sociobiology is a more cautious analysis of the data ...

political judgement, and I suspect he was unsympathetic before he started work on this book. Unlike some other authors, however, he has undertaken a genuine study. He does understand the ideas he is criticizing. He has the biological knowledge to evaluate the evolutionary background to sociobiology, and the mathematical ability to analyse the claims made for it. Above all, he presents sociobiology in its strongest and most coherent form, and avoids the easy option of attacking only its more idiotic manifestations.

He distinguishes sharply between the attempt to understand the evolution of social behaviour in animals, and attempts to understand man. He is sympathetic to the former enterprise. Correctly, he points out that there is no special underlying theory: "There is no autonomous theory of the evolution of behaviour. There is only the general theory of evolution". It may be that interactions between relatives, and frequency-dependent fitnesses, were more important in the evolution of the behaviour of birds than in the evolution of their wings, but they are not peculiar to behavioural evolution: kin selection and game theory are just as relevant to plant evolution.

There is, of course, good and bad work in animal sociobiology, and Kitcher gives examples of both. The bad, he points out, has two characteristics: data are quoted as supporting some specific hypothesis, without considering alternatives, and the hypotheses themselves are modified after the fact until data and predictions are brought into line. However, his chapter "Dr Pangloss's Last Hurrah", which takes issue with the "adaptationist program", seems to me only partly correct. He presents two genetical reasons for not expecting perfect adaptation. The first is that there are genetic systems, even with constant fitnesses, in which selection will not fix the fittest genotype. The simplest is that of heterozygous advantage: if Aa is fitter than AA or aa, selection cannot produce a population consisting entirely of Aa individuals. This is of course true, but is it interesting? If we want to understand why some species does not have the phenotype predicted by theory, this kind of genetic detail is rather unlikely to be the reason. Suppose, for example, we are interested in the shape of vertebrate wings. Aerodynamic theory shows that the optimal shape is usually elliptical. Pterodactyls, however, never had elliptical wings, but no one would explain this by suggesting that, perhaps, only heterozygotes had elliptical wings. The true explanation has to do with the way in which pterodactyl wings were made. Of course, this would be reflected in the absence of certain kinds of heritable variability, but that is not a useful way of thinking about the problem. For phenotypes of the complexity typically discussed by sociobiologists, it is usually better to think at the level of development and physiology than of genetics.

All the same, there will be cases in which this kind of genetic constraint will be relevant. The second kind of genetic constraint discussed by Kitcher, however, seems to me to be a misunderstanding. He points out that when fitnesses are frequency-dependent, the mean fitness of a population may decrease under selection. Therefore, he says, "proponents of optimization analyses who show that a certain design would maximize mean fitness may not automatically assume that selection can produce this design". Now, as Kitcher understands very well, a major thrust of sociobiology has been to show that selection acting at the level of the individual does not necessarily lead to the evolution of characteristics optimal for the population. One of the main reasons for

this is that fitnesses are frequency-dependent. Evolutionary game theory was developed specifically to analyse such cases. It is not sociobiologists who suppose that selection "maximizes [population] mean fitness". It is ironic that the phrase "Pangloss's theorem" was first used in the debate about evolution (in print, I think, by myself, but borrowed from a remark of Haldane's), not as a criticism of adaptive explanations, but specifically as a criticism of "group-selectionist", mean-fitness-maximizing arguments.

Thus I think that Kitcher is unfair to sociobiologists when he introduces the argument from frequency-dependence. However, it is a rare slip: in general his

... It is natural for geneticists and evolutionary biologists to hope that their disciplines will throw new light on the human condition ...

account is just. I agree that what we now need in sociobiology is a more cautious analysis of data, and a more careful consideration of alternative hypotheses. This will not come easily, for reasons that are as much sociological as scientific. The critique by Gould and Lewontin has had little impact on practitioners, perhaps because they were seen as hostile to the whole enterprise, and not merely to careless practise of it. Theorists like myself are understandably delighted when some set of observations seems to fit their theories. Field workers, equally understandably, are pleased if their data receive a rational explanation. The time has come, however, for editors and referees to place more emphasis on the quality of the data, and the care with which alternative explanations have been considered, and less on success in fitting the data to some particular theory. But, as Kitcher insists, the enterprise is worthwhile, and the best work is of a high standard.

What of man? Clearly, biology must have something to say. Man is an animal, and has evolved by the same processes as other animals. The debate is between those who, while accepting that man is an animal, argue that he is such a peculiar animal that evolutionary biology can have little to say about his social behaviour, and those who think that the study of human societies, just as of ant societies, must be rooted in biology. The second position Kitcher refers to as "pop sociobiology". I think this is a pity, for two reasons. First, it gives an image of superficiality and appeal to popular prejudice which, at least sometimes, is quite unfair: it is hard to imagine anyone less "pop" than Richard Alexander. Second, it gives the wrong impression of what Kitcher himself is doing: he is scrupulous about putting the best interpretation on sociobiological arguments. But I see his difficulty: we do need a term for the application of sociobiology to human beings, and I have no better one to offer.

Kitcher's basic position is that one cannot dismiss pop sociobiology simply by asserting that it assumes genetic determinism and is therefore false, since plausible sociobiological arguments can be developed which do not assume that genes determine behaviour. There is therefore no escape from considering these arguments in detail, and to see if they stand up

... one cannot dismiss pop sociobiology simply by asserting that it assumes genetic determination and is therefore false ...

and deliver any fruit. Kitcher distinguishes two schools of pop sociobiology, those of E. O. Wilson and of Alexander. Wilson's basic argument he sees in the form of a ladder, as follows:

(i) We can plausibly argue that the members of some population, G, would maximize their fitness by exhibiting behaviour B.

(ii) If we observe that members of G in fact do B, we conclude that B became, and remains, prevalent through natural selection.

(iii) Because selection is effective only if there are genetic differences, we can conclude that there are genetic differences between current members of G and their ancestors, who did not do B.

(iv) Because there are genetic differences, and because the behaviour is adaptive, the behaviour will be difficult to modify by altering the social environment.

This is a shortened version of Kitcher's reconstruction. A major part of his book consists of a step-by-step critique. Clearly, the last step is based upon the shakiest grounds: the fact that our ancestors did B in all previous environments is not proof that they will do B in a wholly new one. The first three steps look more secure. Kitcher's most effective criticism here is not of the logical possibility of taking these steps, but of the ways in which they are in fact taken. For example, consider sexual behaviour. He quotes Wilson as espousing the view that evolution will lead to males that are "aggressive, hasty, fickle, and indiscriminating", and females that are "coy". But theory suggests not one evolutionary optimum, but several, and a number of our primate relatives form long-term pair bonds and show extensive male parental care. Hence there is little justification for Wilson's first step onto the ladder.

A second illegitimate way of getting on to the ladder is to apply to animals words which describe some human behaviour. For example, mallard drakes are said to "rape" ducks. Now it is true that drakes do force copulations on ducks and, by so doing, probably increase their fitness. What is the harm in calling this rape? If you are interested in ducks, rather little, but if you are interested in people, quite a lot. It implies that human rape occurs because it increases the inclusive fitness of the rapist. The contexts in which rape

occurs makes this implausible. I agree that there is a danger in applying words such as "aggression", "incest", "homosexuality" and so on to animals and man alike, when the behaviours referred to may be quite different. However I do have reservations. The alternative is often to invent a turgid and incomprehensible vocabulary to describe what animals do. I remember our unsuccessful attempt to introduce the term "kleptogamy" at an ethological congress, because we feared that the Anglo-Saxon alternative might offend our hosts.

A few years ago, I worked through the equations in Lumsden and Wilson's *Genes, Mind, and Culture* and found them to be badly flawed. Kitcher has done a still more thorough job, and come to essentially the same conclusion: his chapter is entitled "The Emperor's New Equations". On three occasions Wilson has found it helpful to find a mathematical collaborator. His first two were Robert MacArthur and George Oster: he was third time unlucky.

The second approach to human sociobiology, taken, for example, by Alexander, Irons, Chagnon and Dickemann, is more direct. Man is treated like any other animal. The question asked is as follows: given the social environment, do people behave so as to maximize their inclusive fitness? The answer, it is claimed, is "yes". Unlike Wilson's arguments, which seem to me generally ill-formulated and empty of content, this claim is worth taking seriously, even though it is probably false. Kitcher, attacks it on two fronts. First, he asks what proximate mechanism could possibly bring such behaviour about, since it seems to require an unconscious relationship-calculator and fitness-maximizer influencing our conscious actions. If I were Alexander, I would reply that, if the claim is true, then it is up to psychologists to discover the mechanism.

Kitcher's second line of attack is to ask whether people do in fact maximize their fitness. Here, the test case is Dickemann's account of societies practising female infanticide, and other acts not obviously contributing to fitness. Kitcher gives a careful analysis of this case, and develops a mathematical model of it suggesting that the increases in inclusive fitness that Dickemann proposes would not in fact occur. I am not sure whether he is right, but this is where the action is. This school of sociobiologists do say things about real societies that are testable; I find it hard to believe that they are right, but at least they are not vacuous.

This is an admirable book. Kitcher has the necessary background in biology, mathematics and philosophy. He is aware of his prejudices, and does his best to overcome them. This will not be the last word, but it is the best one yet. □

A case of peripatetic mammaldom

David W. Macdonald

Naturalized Mammals of the World. By Christopher Lever. Longman: 1985. Pp. 487. £40. To be published in the United States late 1985/early 1986, \$79.95.

THE innocent naturalist might relish a glimpse of an elusive mammal as a glimpse of unspoilt nature — a sight that might have brought a thrill in just that place, under just those circumstances, for millennia. Surely mammals, of all creatures, with their unassailable wildness, and secretive and often nocturnal habits, remain untainted by the meddling hand of man, albeit restricted to dwindling enclaves of suitable habitat?

Naturalized Mammals of the World shatters any such illusion that wild mam-

Red deer — now a New World resident.

mals are where they ought to be, or rather where they used to be. The reader will not be many pages into this intriguing catalogue of mishaps before succumbing to the overwhelming impression of a peripatetic mammaldom, of which an astounding array of displaced species are wreaking biogeographical havoc. Most people could name a handful of aliens in their country — in Britain, for example, the grey squirrel and coypu — but common knowledge of the few belies the many less-notorious species which have been deliberately (and, generally, in retrospect, misguidedly) shuffled around the globe. I got up to 67 major introductions before losing count. To qualify for the doubtful distinction of inclusion in the book, a species should have been imported from its natural range to a new country or region either deliberately or accidentally by human agency, and should currently be established in the wild in self-maintaining and self-perpetuating populations unsupported by, and independent of, man.

Apart from a succinct introductory section, and a set of useful tables and appendices, the book is made up of single-species monographs, each of which documents that species' displacement and sub-

sequent misdeeds. An addictive feature of these monographs is the pair of contrasting world maps provided, showing the animal's range "before" and "after" the onset of globe-trotting; the temptation, which I suspect few will resist, is to thumb ahead for a furtive peep to discover whether your favourite species suffers the stigma of far-flung black blobs scattered improperly across the "after" maps. The text itself is an enjoyable blend of biology and history, and is written in a precise and scholarly style. Although the author does not dwell on the implications for ecological theory of the effects of different immigrants on their new habitats, his text draws attention to the extraordinary interest of the process of invasion, and the many "unnatural" experiments that have been inadvertently established worldwide.

The history of three canids illustrates the scope of the book and the variation in the examples it documents. Red foxes were introduced to Australia in the late nineteenth century, in numbers generally no greater than two's and three's, by would-be hunters. Their progress can be charted in detail year by year from local records, until they are now widespread to

the extent that tens of thousands of descendants of the original few are killed annually. (Incidentally, British foxes were also shipped across to populate the eastern United States, and foxes from Spain were imported to bolster the numbers in Britain.) Then there is the raccoon dog, which originated in the Far East. For them, the scale of the operation was quite different. Between 1929 and 1967, 8,651 were released in European Russia by those with an eye on their pelts — in 1947 alone, 1,147 gravid females were let loose in the Caucasus. Each of these cases differs from that of the dingo, which was probably shipped to Australia some 3,000 years ago and so must soon qualify for honorary citizenship.

Although essentially a reference volume, this book has the "Guinness Book of Records" type of appeal to a browser. Apart from serving its main purpose, it will doubtless provide an abundance of worthwhile "Did you know . . . ?" gambits for both amateur and professional naturalists. □

Botanical spread

Brian Mathew

A Guide to the Vegetation of Britain and Europe. By Oleg Polunin and Martin Walters. Oxford University Press: 1985. Pp.284. £17.50, \$25.

AMID the dense rash of wild-flower books dealing with the flora of Britain and Europe at the species level, it is refreshing to be presented with a volume devoted to whole communities of plants. Polunin and Walters are probably accurate in claiming that this is the first attempt to bring together all the information on the subject at a layman's level, although, as they acknowledge, there are many other detailed works covering individual countries or regions.

Accordingly, a helpful bibliography has been included, divided into vegetation types, for those who wish to pursue any interesting points raised in the text. For internal reference, the reader is also well provided for, with indexes to Latin names, English names and plant communities, and a useful glossary (although I was surprised to find no mention, here or in the index, to the commonly used term "downland"). Conservationists, who now tend to put as much emphasis upon the preserva-

tion of habitats as of individual species, will find much useful material is provided, and there is a descriptive list of the Nature Reserves and National Parks throughout Europe.

The opening chapters deal with the all-important subjects of soils and climates, which have a great bearing on the plant cover, and there is an interesting summary of the history of Europe's vegetation from the earliest fossil records onwards. The bulk of the book consists of 14 chapters devoted to different regional zones — Arctic, Mediterranean, Central Europe and so on — and, within these, there are subdivisions down to communities with examples of the species to be found in them. The text is supported by many good line drawings and a few rather poorly reproduced monochrome photographs; the latter, however, are more than compensated for by the 110 excellent colour plates of vegetation types.

The authors have faced a difficult task, and it is not surprising that the book may appear bitty at first sight. As with most aspects of the botanical world, the demarcation lines are often ill-defined and there is much overlap, for example between *maquis* and *garigue*, with several different types of each of these. To have presented an over-classified statement of the situation would have led to many inaccuracies, and it is to the particular credit of Walters and Polunin, given the intended audience of their book, that they have struck the right balance between the superficial and the overlearned. □

Brian Mathew is a Principal Scientific Officer in the Herbarium, Royal Botanic Gardens, Kew, Richmond, Surrey TW9 3AB, UK.

Animals and plants first

Michael J. Bean

International Wildlife Law. By Simon Lyster. *Grotius, Llandyssul, Dyfed SA44 4BQ, UK: 1985. Pp.470. Hbk £25, \$37; pbk £12, \$17.50.*

THE earliest efforts at international cooperation in the conservation of living resources date back well into the nineteenth century. Since then, the number of international treaties and agreements aimed at conserving wildlife has grown steadily. Not until Simon Lyster's book, however, has anyone tried to offer a comprehensive analysis of that body of law. The result is a compelling display of legal scholarship that should reward scientists interested in policy matters and conservationists around the world.

This is a book by a British lawyer about international conservation law. It escapes, however, the trap of appealing only to a narrow audience of similar specialists. After an introductory chapter that provides a layman's overview of certain general principles and characteristics of international law, Lyster turns his attention to a series of wildlife treaties. For each of these he offers some historical background, including a discussion of the problems that the treaty was intended to address, a detailed analysis of the terms of the treaty, and an assessment of the treaty's actual implementation and effects.

The most remarkable aspect of the book is its sheer scope. It is not limited to the treaties of a particular country or geographical region, and reaches out across ocean barriers to encompass the Convention on Nature Protection and Wildlife Preservation in the Western Hemisphere (1940), the African Convention on the Conservation of Nature and Natural Resources (1968), a pact of 1969 among Andean nations for the conservation of the vicuna, an agreement of 1973 among circumpolar nations for the conservation of the polar bear, numerous European treaties for the conservation of birds and other wildlife, and yet other initiatives.

The most thorough analysis in the book is devoted to four treaties of the 1970s that Lyster calls "the centrepiece of international wildlife law": the Convention on Wetlands of International Importance Especially as Waterfowl Habitat (1971); the Convention Concerning the Protection of the World Cultural and Natural Heritage (1972); the Convention on International Trade in Endangered Species of Wild Fauna and Flora (1973); and the Convention on the Conservation of Migratory Species of Wild Animals (1979). The complete texts of these and eight other treaties are reprinted in full in

● *Flowering Plants of the World*, consultant editor V. H. Heywood, which was published in 1978 by Oxford University Press and has been out of print, has been re-issued by Croom Helm in Britain and Prentice-Hall in the United States. Price is £19.95, \$39.95.

an appendix that occupies nearly a third of the entire volume.

The criteria upon which Lyster bases his judgement that the four treaties he principally addresses are in fact the most important are unstated. All are indeed global, open for signature by any nation of the world, but only two, the World Heritage Convention and CITES (the Endangered Species Convention), have the adherence of a majority of the world's nations. The Migratory Species Convention may be the most recent of international conservation initiatives, but with only 15 party states and no real accomplishments to date, Lyster's claim that it occupies part of the "centrepiece of international wildlife law" is premature at best. The Wetlands Convention, though it has served to direct attention to a particularly pressing problem; is notable mostly for its failure to create clear, enforceable obligations. While it is dealt with elsewhere in the book, the International Convention for the Regulation of Whaling might more properly have been included in the centrepiece if world attention and actual results were the criteria for that uncertain distinction.

A recurring theme throughout the book is the wide, sometimes enormous, gap that separates the aims and apparently literal meaning of most of these treaties and their actual implementation. For example, the World Heritage Convention tries to come to grips with the reality that many of the world's great cultural and natural resources are in the countries least able financially to assure their protection or forego the short-term benefits associated with their exploitation. The mechanism fashioned to answer this dilemma is, through the creation of a trust fund, to transfer wealth from the developed to the developing world for purposes of conservation. Though there is nearly universal agreement that such a transfer is needed if the intentions of the Convention are to be realized, the actual amounts of money made available for the purpose have been so small as to undermine any confidence that the commitment to the principle is anything more than cosmetic. Beyond noting the fact of such gaps between promise and performance, Lyster does not delve into explanations or suggest possible solutions.

His book stands, however, as an impressive survey of some of the efforts at international cooperation made over the past century to stem the loss of wildlife. It is, at the same time, a depressing reminder of how short many of those efforts have fallen. □

More Darwinian detractors

Mark Ridley

Evolution: A Theory in Crisis. By Michael Denton. Burnett, London: 1985. Pp.368. £17.50. To be published in the United States in April 1986 by Adler & Adler, Washington, DC.

Creation and Evolution: The Facts and Fallacies. By Alan Hayward. Triangle, London: 1985. Pp.232. Pbk £2.75.

Adam and Evolution. By Michael Pitman. Rider, London: 1985. Pp.268. £9.95.

Evolutionary Theory: The Unfinished Synthesis. By Robert G.B. Reid. Croom Helm/Cornell University Press: 1985. Pp.405. £25, \$34.50.

WRITING a review of some long since forgotten anti-Darwinian work in this journal 95 years ago, Raphael Meldola remarked that "it is hardly necessary to say that many of the most weighty objections have been culled from the writings of Darwin himself". *Toutes ces la même chose*. Another four books published during 1985 now confirm that Mr Darwin's critics are as active, and their procedures the same, as ever. I do not think it is worth replying to them here. Readers of *Nature* can scarcely need to be put right on these old issues; and, anyhow, Darwin himself and many others have dealt with them at the length they deserve. How can I hope to succeed with three authors (Denton, Hayward and Pitman) who, like the Victorian astronomer Sir John Herschel, think that evolution by natural selection is the "law of higgledy-piggledy" — a "random search mechanism" (Denton), of "pure chance" (Hayward and Pitman)? Or with another author (Reid) who, like the Duke of Argyll, thinks that there must be some grave defect in Darwin's theory, because it personifies Nature in its analogy with artificial selection?

Denton, Hayward, Pitman and Reid, then, are opposed to the Darwinian theory. The first three of them (as we shall see) object to it for similar reasons; but they differ in what they would put in its place. Hayward is a creationist and Christian. Pitman is a creationist too, and probably a Christian one, although he has heretical leanings towards the dualistic (not trinitarian) wisdom of the East and an enthusiasm for music mysticism. Denton's purpose is purely destructive: he has no alternative to offer. Reid thinks he has a secular alternative, which we shall come to. His is the only book of the four that is written in a cerebral style, for an audience of professionals of some kind. Denton, Hayward and Pitman all write for uninformed readers, the latter two in the kind of short, didactic sentences and superficially patient tone that, in Britain, one associates with the closed minds of their

school. Denton has a different style. His pen is constantly running out of control. Every few pages he treats us to some more or less silly exaggeration. The preface sets the tone by telling us that "every aspect of evolution theory is being debated with intensity", at conferences, in journals and in the Natural History Museum in London. Denton may think that exaggeration is a necessary part of popular writing. If so, he is wrong.

None of the authors is an evolutionary biologist. Denton is a biochemist; Reid a philosophical physiologist; Hayward a retired physicist; Pitman "has an MA in classics". They would not think this a disadvantage. A Darwinian education (they believe) cripples the mind, filling it with emotional prejudices. Hayward accordingly prefers the unbiased view of the "outside observer", and Bernard Stonehouse without irony recommends Pitman to us as follows: "his unorthodox background must have helped Michael Pitman to write this book; it might not have occurred to one formed in a more conventional mould".

Their procedure is to sift through the writings of Darwin, and such popular secondary and tertiary sources as Stephen Gould's essays, *New Scientist* and even *The Guardian*. From this material, they seize upon the bits that look like difficulties for Darwinism, and ignore everything else. Then, after surrounding the difficulties with schoolroom rhetoric, sub-Kuhnian psychobabble and suitably simplified Victorian history, they send the whole to press. As argument, indeed, all four books are sad stuff. The reasoning I shall come to, but mark well the style. Denton is especially keen on the device (it must have a technical name) "even Darwin-Simpson-Sir Peter Medawar admits-concedes-acknowledges that . . .", which he places before each attenuated quotation, in order to reverse their meanings. I similarly found myself, in Hayward, "grudgingly admitting" something that in reality I unhesitatingly espouse. Denton's characterization of Lyell provides another example. "For most of his life", we are told — and this is all we are told — "[he] was vigorously opposed to the idea of evolution".

So why do Denton, Hayward and Pitman object to the neo-Darwinian theory? Their case (the arguments of the three are similar) is essentially Victorian. It plays on two main "difficulties": "chance" and "gaps". Natural selection, they all allow, can cause small changes in simple adaptations; but they deny that it can cause large changes among types and the evolution of complex adaptations like the vertebrate eye. "Different processes altogether may be involved, and here Darwin's strength fails" (Pitman). As they have identified natural selection with chance, they deduce (correctly) that it could not in principle produce large directed changes. Only the premise is wrong. In the Darwinian

theory, natural selection is not a chance process and complex adaptations evolve in many small changes. That possibility they either silently ignore, or misunderstand and quickly brush aside.

Then we have the problem of gaps. There are gaps between the classes of modern forms, and those well-publicized gaps in the fossil record. The origin of life is an example. According to these authors, it would not be possible for evolution by natural selection to cross the gap between the non-living and the living. After all, where are the intermediate forms? They have not been found, even though, according to Pitman, "billions of dollars are spent annually in attempts to demonstrate abiogenesis under laboratory conditions". Pitman also quotes Francis Crick, who "admits" that "regarding the origin of life we often find 'too much speculation running after too few facts'"; but speculative pursuit is as ill-advised when the aim is to demonstrate a negative, as a positive, conclusion. Darwin's own remarks about difficult transitional stages — that they are a problem of the imagination, and not of the reason — is silently ignored, but implicitly illustrated.

The theory of "punctuated equilibrium" of Eldredge and Gould here again does time for the creationist cause; but the Darwinian view (and that of Eldredge and Gould although they do not like to say so), that the gaps of the fossil record are due to its incompleteness, is scarcely discussed. The gradualism of Darwin, which applies not to rates of evolution but to the evolu-

tion of complex adaptation, is misunderstood by all the authors.

They have other objections too. For instance, they have all learned, from the popularizations of Sir Karl Popper and others, that natural selection is a circular argument (although Denton has still to learn from Pitman that Popper has "to some degree relaxed his position in a way that favours Darwinism"). And Denton thinks that natural selection cannot explain homology, including serial homology which "cannot by any stretch of the imagination be explained by descent from a common ancestor".

In the case of the two main objections I have dealt with, the authors have neglected the answers put forward by Darwin and his followers. Why should this be? Maybe they are unaware of them. Maybe they think only the devil needs an advocate. The texts, however, point to a third reason. The typical Darwinian of these pages is a man incapable of rational argument. Neo-Darwinism (we are told) is an "article of faith" (Pitman), a "belief-web" (Reid), a "paradigm" of "illusion" and "dogma" (Denton). It is believed in, and defended against critics, only because of "emotional commitment" and "extra-scientific factors", which are to be understood by the "sociology of knowledge". When the dogmas of neo-Darwinism are threatened, for instance by neo-Lamarckism, its fanatical adherents do not react with rational scepticism, about dubious factual claims. They remorselessly persecute the poor heretics, until they are driven into suicide or emigration, and

then trumpet their triumph in a ritual of collective orthodoxy. The doctrine of neo-Darwinism is thus seen as establishment cant, not rational science, and therefore hardly merits serious consideration. The critic may save himself the trouble, and ignore it.

Reid is a rather different kettle of fish. His purpose is not, for the most part, destructive. He does include a chapter on some of the "difficulties" in Darwinism, and he notices others from time to time. The main problem, he believes, is that Darwinism is "reductionist" and has therefore "shied away from explaining the emergence of meaningful wholes from individually meaningless parts". It also suffers from two previously unnoticed defects: a new kind of circularity, and the "homeostasis paradox" ("if homeostasis is characterized as constancy, and evolution characterized as change, how did the homeostatic condition evolve?"). The circular argument is this:

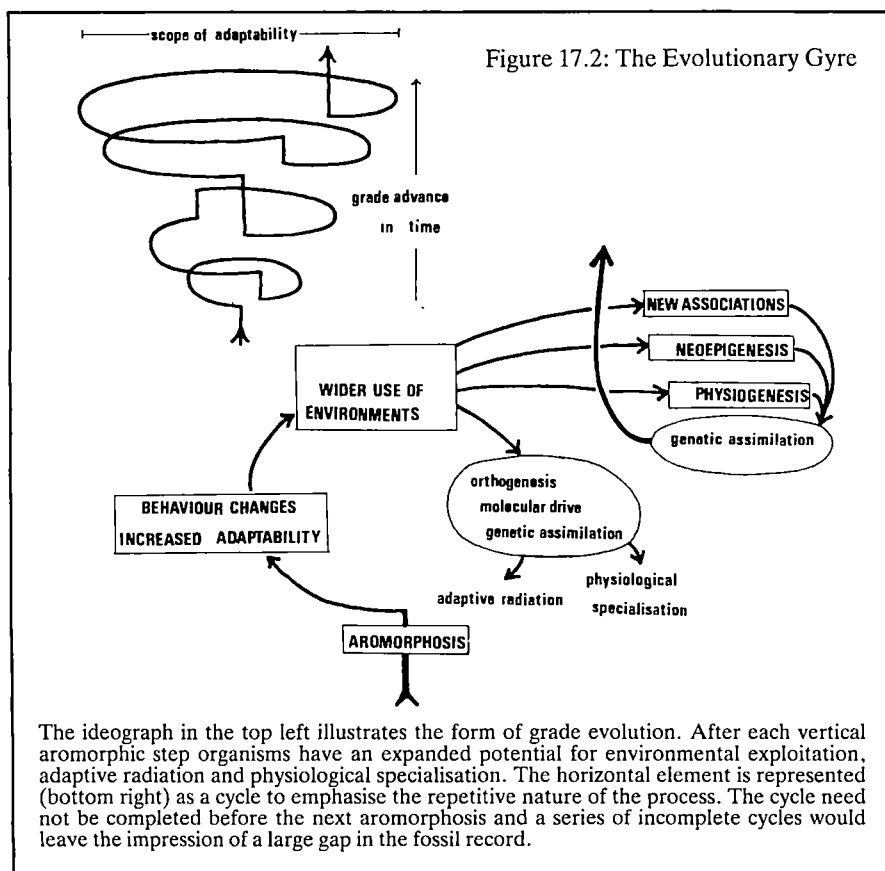

Descent by modification through natural selection was Darwin's slogan. This linkage of two independent ideas was the core of Darwin's thesis and claim to originality, although it involved the circular argument that evolution occurs because of natural selection, therefore natural selection must operate; natural selection operates, therefore evolution must result.

Reid does not name names here, which is a pity because I cannot think of anyone who has fallen into this error.

But Reid's main purpose, as I have said, is positive. He was woken from his Darwinian slumbers by the student rebellions of the late 1960s and a reading of Thomas Kuhn. He duly discovered an alternative paradigm, of holists, and it is his aim in his book to introduce us to them. He has arranged people such as Driesch, Woodger, Bergson and von Bertalanffy into convenient groups; for each he gives some biographical details and summarizes their attitudes. They are in favour of emergence, integrative hierarchies and all that sort of thing. Anyone who is looking for an introduction to these people may find the book useful. But no one else will, because it is neither historical nor argumentative; it does not put their opinions in context nor does it try to show us that they were right.

Reid ends by expounding his own holistic alternative. It defies short summary, but fortunately he illustrates it with some figures, the most important of which is reproduced (left). Reid does not like neo-Darwinians, who do not treat all his friends and their enthusiasms with sufficient gravity. But now we have an opportunity to set things right. We should add the "evolutionary gyre" to our introductory lectures, expose our students to the alternative paradigm, and treat it with the seriousness it deserves. □

Holding back on dangerous play

Lawrence Freedman

Superpower Games: Applying Game Theory to Superpower Conflict. By Steven J. Brams. *Yale University Press: 1985.* Pp. 176. Hbk \$31.50, £22.50; pbk \$9.75, £6.95.

THERE was a time when game theory was all the rage in the strategic studies community. This was the "golden age" of strategic studies—the late 1950s and early 1960s—when it was fresh with new ideas and insights on how best to deal with the nuclear dilemmas that were perplexing policy-makers.

Game theory was ideal in two ways. First, it offered a methodology of some sophistication with which to challenge the traditional approaches to strategic issues based on history and politics and military experience. All of these were now deemed to be irrelevant in the nuclear age. Second, the assumptions behind game theory fitted in with the predispositions of the new generation of strategists. It was not that they saw superpower conflict as a "game"; the term only really referred to the idea of structured situations in which the ability of either "player" to achieve his best outcome depended on decisions taken by the other.

Superpower conflict at the time seemed to be suited to game theory for three reasons. First it involved two sides who were deeply antagonistic and likely to be so for the foreseeable future: there was no risk of the game dissolving in an outbreak of peace and harmony. Second, despite this, the antagonism was incomplete. There was some common ground—to take the most obvious, a mutual interest in the avoidance of an outbreak of nuclear war. Third, as on the one hand the two sides were engaged in a contest for power and influence in the world, while on the other a nuclear war in which both would be devastated was the most likely result of any attempt to resolve differences through military means, it was useful to have a tool for identifying the solutions that logic might lead both powers to adopt in particular types of situation. If some solutions pointed to disaster then corrective action would need to be applied.

Within its limits game theory was quite valuable. It served as a means of emphasizing the extent to which superpower confrontation did not necessarily mean that one gained what the other lost (zero sum-games) but that there could be circumstances in which both won or both lost (non-zero sum games). It drew attention to the extent to which in non-zero-sum games both sides might tend towards the best of the worst solutions (minimax). Following through the logic of certain games

could illuminate aspects of the real dilemmas that the superpowers faced. But the approach did have its limits: the individual games had to be simplified in order to keep them manageable and a presumption of rationality had to be made. Moreover, the results of the games depended critically on the assumptions made as to the choices available to the two sides, and the values attached to the alternative outcomes (payoffs).

Accordingly the best exponents of game theory (notably Tom Schelling) never allowed themselves to be restricted by the theory and were often at their most effective in using it only as a starting point for a broader analysis. Those who had dabbled with it when fashionable soon lost in-

Pershing II missile — large chip in a deadly game.

terest. Nevertheless a number of scholars have persisted with the development of the technique.

Steven Brams is one such scholar who has worked hard to extend the range and applications of the basic theory. This book, which is made up of previously published articles, updated and reworked to give them some coherence, contains the results of his work. He is an unqualified believer in its continuing relevance. In the concluding chapter he states: "The evidence seems to me, incontestable that game theory captures a substantial part of the logical basis and empirical reality of superpower conflict and provides a unified framework for its analysis" (p. 145).

This case can be assessed by examining the quality of the analysis and then the value of the conclusions. For the first, it has to be said that Brams makes few concessions to his reader. He does not attempt to justify his methodology against the standard objections or to introduce it for a lay reader. The mathematics is hard work for those (such as myself) who are

out of practice, and the argument is tight. So all that can be said, with the utmost humility, is that it seemed fine to me.

Much of the development of theory in this book constitutes an attempt to catch up with the empirical reality, and this accounts for much of the complexity of the argument. One means by which this is done is to test the theory against case studies such as the Cuban missile crisis of 1962 and the nuclear alert during the concluding stages of the 1973 Yom Kippur War. One concept of which Brams appears to be especially proud is that of "nonmyopic calculation" which essentially shows (if I have understood it correctly) how a different outcome is achieved when the belligerents are encouraged to take a long-term view and are not dominated by short-term considerations.

The question, however, is whether empirical reality is driving the theory to explain in complicated ways what might be explained more simply by more straightforward methods, or whether the theory can tell us something new. At times it is indeed illuminating but not to anything like the extent the author appears to believe.

In the end Brams suggests that the opponents act the way they do because of the "rules of the game" rather than because of anything very fundamental in the two sides' make-up. This seems to me to be going too far. It may be that the logic of the situations in which "players" find themselves influences the character of their choices, and the way those choices are made cannot be understood solely by reference to the rules of the game. Moreover, in structuring the games themselves, Brams makes some rather arbitrary judgements on the nature of the choices. For example, over Cuba, the options given for the United States are to blockade or to strike at the Cuban bases, and for the Soviet Union to retain the missiles or withdraw them. This does no justice to the actual range of choices—the United States might have done nothing; the Soviet Union might have escalated matters to take in Berlin. In the three basic issues Brams tackles—deterrence, arm-races and verification—only one dimension of the problem is addressed and the way that the problem itself is defined is controversial. On the whole the proposals at the end of the book are sensible, which gives one greater confidence in the analysis, but they are by no means wholly original and could have been arrived at by simpler methods.

In short Brams has demonstrated his skill as an exponent of games theory, and its continuing if modest value as an aid to working through the logic of superpower conflict. He has been far less successful in justifying the somewhat grandiose claims that he makes for the enterprise. □

AUTUMN SHOWCASE

Principles of Neural Science

Second Edition

Editors:

Eric R. Kandel, M.D.

The Howard Hughes Medical Research Institute and Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University

James H. Schwartz, M.D., Ph.D.

The Howard Hughes Medical Research Institute and Center for Neurobiology and Behavior, College of Physicians and Surgeons, Columbia University

The expanded, completely updated new edition of **Principles of Neural Science** will be available in the fall of 1985. Like its predecessor, this new edition applies the insights gained from current research in basic science to the study of the nervous system, its development, and its control of behavior. The second edition places an even stronger emphasis on cell and molecular biology and includes a new and systematic treatment of neuroanatomy as it relates to neurobiology and behavior, detailed enough to serve as a foundation for clinical neurology and psychiatry.

1985 1,032 pages cloth \$ 47.50 in North America/£ 40.00 in the United Kingdom/Dfl. 160.00 outside North America and the U.K. ISBN: 0-444-00944-2

Renal Biochemistry

Cells, Membranes, Molecules

edited by R. K. H. Kinne

This book contains the first compilation of current knowledge on the biochemical reactions occurring in the kidney at the cellular and subcellular level.

It has two major features, the first being that it is a result of the methodological progress that has been made during the last decade to overcome the heterogeneity of the renal cells. Thus, an analysis of the various renal cells, without interference from reactions occurring in other cells, has become possible.

Secondly, the book reflects the change in concept regarding the biochemistry of the kidney. The contributions were purposely chosen to represent not only biochemical reactions related to the transport function of the kidney, but also to take into account the role of the kidney in detoxification and its role as an endocrine gland.

1985 476 pages
Price: US \$ 125.00/Dfl. 339.00

Pharmacological and Chemical Synonyms

8th Revised Edition

Compiled by E. E. J. Marler

This is the latest edition of the worldfamous listing of pharmaceutical and chemical synonyms, including pesticides, which was compiled for the first time in 1956. The book is the most comprehensive source of its kind as more than 4,000 medical and pharmaceutical journals are continually screened for new compounds through the

Excerpta Medica Database. The contents of the book have been converted into a special database to which every new substance name is added, so that the latest information will always be available. The listing now contains approximately 12,000 main terms and all their synonyms.

For people working in the field of pharmacology, pharmaceuticals and toxicology, as well as for medical editors and drug regulatory officers, this work will prove to be an indispensable source of information.

1985 642 pages
Price: US \$ 90.75/Dfl. 245.00

The Antimicrobial Agents Annual 1

edited by P. K. Peterson and J. Verhoef

THE ANTIMICROBIAL AGENTS ANNUALS, VOLUME 1

The Antimicrobial Agents Annual 1 evaluates 35 groups of new antimicrobial chemotherapeutic drugs and gives critical state of the art reviews of 12 topics of current interest. The authors reviewed some 6,000 articles, 2,000 of which have been used to compile Annual 1. Only those agents and topics are now covered which present some problems of judgement in the dynamic field of antimicrobial therapy. The analyses given by the expert authors is based on information published in the 18 month period preceding publication and will be of interest to infectious diseases specialists, microbiologists and investigators of the pharmacology and chemistry of antibiotics. This volume is an indispensable reference work which should be used as an update of all standard texts by everyone involved in treatment and research of infectious diseases.

1986 approx. 600 pages
Price: US \$ 69.00/Dfl. 200.00

The Electrophysiology of the Secretory Cell

edited by A. M. Poisner and J. M. Trifaró

THE SECRETORY PROCESS VOLUME 2

Series editors: A. M. Poisner and J. M. Trifaró

It is the purpose of this series to explore the current understanding of the biology of secretion without restriction to a specific regulatory system (endocrine, exocrine), level of organization (cellular, subcellular), chemical mediator (calcium, cyclic AMP), experimental approach (electrophysiological, morphological), or even to conventional secretory cells. Information from studies on non-mammalian, invertebrate or even plant physiology should prove useful in understanding the features of the secretory process.

This second volume is devoted to the electrophysiology of the secretory cell due to the critical mass of information accumulated over recent years which clarifies the relation of bioelectrical events to secretory activity.

1985 xviii + 312 pages

Cloning Vectors:

A Laboratory Manual

edited by P. H. Pouwels, B. E. Enger-Valk and W. J. Brammer

This manual, the very first comprehensive compilation of currently existing vectors used in cloning, will serve in rapidly identifying a given vector best suited for a particular purpose. A large section of this book is devoted to *Escherichia coli*, the most commonly used for general cloning and manipulation of DNA sequences. However, other gram-negative bacteria are discussed as are several gram-positives such as *Bacillus subtilis*, the genera *Staphylococcus* and *Streptomyces*, the lower eukaryotic yeasts and fungi, and animal and plant cells in culture.

Volume 1

1985: Approx. 400 pages

Progress in Protein-Lipid Interactions

edited by A. Watts and J. J. H. M. De Pont

PROGRESS IN PROTEIN-LIPID INTERACTIONS, VOLUME 1

Progress in Protein-lipid Metabolism is an international review series designed to critically evaluate actively developing areas of research into the interaction of proteins and lipids in membranes.

The first volume contains new and possibly unpublished data, contributed by active specialists in the field, resulting in a novel approach to future understanding of membrane biology.

Both the biophysical and biochemical aspects of the subject have been covered in a balanced way, in order to provide established workers with a fresh insight into their own particular interest, and new researchers with up-to-date information on this fascinating topic.

Checks on the spread

Gordon Thompson

Nuclear Proliferation Today. By Leonard S. Spector. *Vintage, New York: 1985. Pp.478. Pbk \$5.95.*

Non-proliferation: The Why and the Wherefore. Edited by Jozef Goldblat. *Stockholm International Peace Research Institute/Taylor & Francis: 1985. Pp.343. £11, \$19.*

Safeguarding the Atom: A Critical Appraisal. By David Fischer and Paul Szasz. Edited by Jozef Goldblat. *Stockholm International Peace Research Institute/Taylor & Francis: 1985. Pp.243. £16, \$28.*

Most people would agree that the world will be safer if membership of the nuclear weapons club does not grow. Likewise, most seem to think that we would all be better off if the present members were to stop their frenzied arms race.

Thus we are faced with a problem of nuclear proliferation in two basic dimensions — "horizontal", which refers to the acquisition of nuclear weapons by additional countries, and "vertical", which refers to increases in the sizes or capabilities of existing nuclear arsenals. (We owe this terminology to Indian diplomats who, in the 1960s, coined the term "nuclear proliferation" specifically to link the two dimensions.) The three books reviewed here, if taken together, provide an up-to-date and comprehensive picture of the state of nuclear proliferation, although only in its strictly horizontal dimension.

With Leonard Spector's book, the Carnegie Endowment for International Peace (based in Washington, DC) has launched a series of annual reports on the spread of nuclear weapons. *Nuclear Proliferation Today* provides an account of the proliferative activities of eight "problem" countries — Argentina, Brazil, India, Iraq, Israel, Libya, Pakistan and South Africa — together with discussions of the role of China, and of the status of controls and safeguards on nuclear technology. The eight nations, using a variety of approaches to getting the necessary materials and technology, either have nuclear weapons already or are seeking to acquire them. India publicly acknowledged its nuclear test in 1974, although labelling it a peaceful explosion. Israel, which may or may not have conducted a test, is generally believed to have a few tens of nuclear weapons, perhaps kept in a disassembled form in times of peace. The other six nations are in more ambiguous positions or are less advanced in their quest for a Bomb.

Two of the eight countries (Iraq and Libya) have signed the Non-Proliferation Treaty (NPT), although they apparently do not feel bound by its provisions. The others have refused to sign, generally

arguing that the NPT is discriminatory and seeks to perpetuate the dominance of the nuclear powers.

Nations have had a variety of motives for their decisions to sign or to stand aloof from the NPT. For representative groups of countries, these motives are explored in *Non-proliferation: The Why and the Wherefore*, a collection of essays describing the domestic, international and technical factors which brought each country to its decision. The group of NPT non-signatories studied includes two nuclear-weapon states (China and France), all the non-NPT "problem" countries mentioned above, and Spain. Representing the NPT signatories is a group of six countries ranging from Canada (which has never sought an independent nuclear arsenal) to Taiwan (where plans to build a reprocessing plant were abandoned following heavy pressure from the United States in 1976).

For the book, the Stockholm International Peace Research Institute (SIPRI) has assembled a stable of well-qualified authors (many of them citizens of the countries they discuss) and, to assist in framing the conclusions presented in the overview chapter, the Institute held a workshop in October 1984, attended by a separate group of international experts. Also, SIPRI has drawn on its own resources to prepare several detailed appendices, including one which provides a thorough account of the nuclear infrastructure in each country considered (although the data for China and France are badly out of date).

Comparatively speaking, the conclusions of both SIPRI's study and of Spector's more narrowly focused book are mildly encouraging; that is, the present pace of horizontal proliferation is slow compared with the pace of vertical proliferation. In part, this is because of the emergence of a broad international consen-

sus that the nuclear club should not grow. From this has flowed both moral pressure and the ability to impose an international non-proliferation regime which has complicated the task of any nation seeking nuclear capability. Moreover, the financial costs and technical problems of acquiring an arsenal of nuclear weapons and appropriate delivery systems have proved formidable for developing nations. Finally, growth of the nuclear power industry has been much slower than anticipated; in consequence, possession of a complete nuclear fuel cycle (with the concomitant possibility of diverting fissile materials from reprocessing or uranium enrichment plants) cannot be economically justified for any country, particularly a developing nation.

Central to the non-proliferation regime is the safeguards system operated by the International Atomic Energy Agency (IAEA). This system is the main subject of another SIPRI book, *Safeguarding the Atom: A Critical Appraisal*, which has as its principal author the former IAEA official David Fischer. It also contains a section by Paul Szasz (also formerly with IAEA) and other sections and detailed appendices prepared by SIPRI.

The safeguards laid down by the IAEA are supplemented by other arrangements. First, the Treaty of Tlatelolco, which seeks to make Latin America a nuclear-free zone, is based upon IAEA regulations but also provides for special inspections by a regional agency in the event of suspicious activities. Secondly, the European Economic Community has its own internal system of EURATOM safeguards, which rather wastefully duplicates that of the IAEA. Then there is the Nuclear Suppliers' Group, often known as the London Suppliers' Club, a group of those nations which dominate the export of nuclear materials and technology and which have agreed not to supply certain items

Cartoon featured in *Arms in the '80s*. By John Turner and SIPRI. *Taylor & Francis, London and Philadelphia 1985.* (Taken from the *Mineapolis Star and Tribune*.)

MASSON

Introduction à une biologie des populations

par J.-M. LEGAY et D. DEBOUZIE

1985, 152 pages
2-225-80619-5, 119 FF

The only book, written in French, that treats of population matters, in terms of structure, sociology, genetics and biology.

Table of contents

Les structures de socialité. Les structures spatiales. Les structures temporelles. Les structures génétiques. Les structures de parenté. Conclusions générales. Index.

Membranes biologiques

Structure, transports, bioénergétique
par E. SHECHTER

1984, 232 pages
2-225-80367-6, 145 FF

This textbook describes three main aspects of biological membranes - structure, transport, bioenergetics - which control most of their other functional properties.

Table of contents

STRUCTURE ET DYNAMIQUE STRUCTURALE. Lipides membranaires. Conformation des chaînes hydrocarbonées des lipides. Fluidité membranaire. Diffusion latérale des lipides et des protéines. Mobilité et asymétrie transversales des constituants membranaires. Protéines membranaires : extraction, structure, reconstitution.

TRANSPORTS Rappels de thermodynamique en relation avec le transport. Diffusion passive non ionique. Transport de l'eau. Diffusion ionique. Différence de potentiel électrique transmembranaire. Diffusion facilitée. Transports actifs.

BIOÉNERGETIQUE MEMBRANAIRE. Le concept chimiosmotique. Rappels d'oxydo-réduction. Chaîne de transfert d'électrons (membrane interne mitochondriale). Premier couplage entre transfert d'électrons et transport de protons (membrane interne mitochondriale). La différence de potentiel électrochimique de protons. Deuxième couplage entre diffusion facilitée de protons et synthèse d'ATP (membrane interne mitochondriale). Autres systèmes membranaires siège des conversions d'énergie.

75006 Paris, FRANCE.

unless the recipient nations agree to safeguards (the list of sensitive items is similar to the so-called "Zangger Trigger List", drawn up by a committee of nuclear suppliers chaired by Claude Zangger of Switzerland). Finally, there are the arrangements made by individual countries, of which the most important is the United States Nuclear Non-Proliferation Act of 1978.

The NPT and IAEA safeguards, together with these other arrangements, constitute the non-proliferation regime. As mentioned above, the regime has been helpful in restraining horizontal proliferation: much of the nuclear industry outside the nuclear weapon states is under safeguards, as described in detail by David Fischer, while the "problem" countries generally find it difficult to obtain materials and technology for their weapons programmes. Yet, the future stability of the regime is in question.

As both SIPRI books acknowledge, without pursuing the point, the non-proliferation achievements of the past 20 years could be swept away by changing circumstances. First, the NPT remains in force only until 1995 and it is by no means clear that the treaty will be renewed or replaced by a better arrangement at that time. Many signatories are dissatisfied with the failure of the nuclear-weapon parties (the United States, the Soviet Union and Britain) to live up to their side of the bargain — that is, to end their nuclear arms race. Secondly, regional instability could precipitate a rush of nuclear competition between certain powers. Pakistan and India, for example, could fall prey to such competition, and the tension between these two nations illustrates some important linkages of proliferation. American and Soviet nuclear competition has fed the Chinese nuclear build-up. In turn, this has contributed heavily to India's flirtation with the Bomb. Pakistan has reacted, and thereby fed the fears of Israel about an Islamic Bomb. To compound these linkages, China has apparently assisted Pakistan in its quest for nuclear weapons.

An unavoidable conclusion of all this is that nuclear proliferation cannot be considered in just one dimension. Equally, it is hard to envisage any substantial improvement in the horizontal dimension without progress on control of vertical proliferation. In this respect, all three books are deficient. In particular Leonard Spector reflects the view that proliferation is something which other nations do. This attitude, common in the United States, is perhaps understandable given America's role in constantly raising the qualitative level of vertical proliferation. While SIPRI, as befits its fine record of analysing military activities of all kinds, provides a more balanced view, *Non-proliferation: The Why and the Wherefore* does not really pursue the matter of cross-dimensional linkages.

Readers seeking to understand vertical proliferation have the choice of a vast literature, but at some point would be well advised to consult William Arkin and Richard Fieldhouse's *Nuclear Battlefields: Global Links in the Arms Race* (Ballinger, 1985) which provides a succinct summary of how the nuclear confrontations of the five major powers proceed in a myriad of ways. By outlining the vast global infrastructure which supports development, testing and deployment of nuclear weapons, the book makes clear that the implications of vertical proliferation reach further than we might think.

Two examples are instructive. First, through their participation in the Eastern and Western blocs, NPT signatories can function almost as though they had never signed the treaty. Indeed, six NATO countries which are supposedly "non-nuclear" by virtue of being NPT signatories, and four Warsaw Pact countries in the same position, have numerous delivery systems certified to fire nuclear warheads. When needed, the weapons will be released to them by their nuclear-armed allies. Secondly, the intelligence, targeting, basing, training and communications infrastructure for the nuclear arsenals is spread around the globe, taking in many countries which fancy themselves "nuclear-free" and making a mockery of the idea of nuclear-free zones.

If the non-proliferation edifice begins to crumble, we will rapidly become aware of a third dimension of proliferation. This, the "latent" dimension, refers to the growing ability of many nations rapidly to field a nuclear arsenal should they so decide. The necessary materials and expertise are becoming more generally available as a result of nuclear power programmes. In particular, the wide adoption of nuclear fuel reprocessing and the development of new enrichment technologies imply the stockpiling of large quantities of fissile materials. Despite the lack of economic justification, industrial nations, including Japan and West Germany, are pressing ahead in these areas. Since appropriate nuclear weapon delivery systems are readily available, such nations could field large arsenals with surprising speed. But again, this possibility is discussed in none of the three books reviewed here.

Viewed from a wider perspective, then, nuclear proliferation is a far more serious problem than the strictly horizontal trends of recent years might suggest. It is not alarmist to say that we urgently need to tighten international controls on all forms of proliferation. The current non-proliferation regime provides a basis for doing this, but the world community needs to find the vision to adopt substantial reforms. □

Gordon Thompson is Director of the Institute for Resource and Security Studies, 27 Ellsworth Avenue, Cambridge, Massachusetts 02139, USA, and coordinator of the IRSS Proliferation Reform Project.

WINGS IN THE SEA The Humpback Whale

LOIS KING WINN
and HOWARD E. WINN

An excellent introduction to the humpback for whale watchers, armchair naturalists, scientists, and environmentalists alike. The first comprehensive book for the layman devoted to a single species, it brings together current information on whales, much of it never before published outside the scientific community. This handsome book contains history, legends and folklore, material from logbooks of whalers and explorers, and vivid personalized accounts. 52 photos. 12 line drawings. £15.95/\$19.25 paper, £25.00/\$30.00 cloth

THE ATLAS OF BREEDING BIRDS OF VERMONT

SARAH B. LAUGHLIN
and DOUGLAS P. KIBBE

America's first breeding bird atlas is now available. Birds have long been known as reliable environmental indicators; therefore close monitoring of their nesting status provides invaluable ecological data. This pioneering work defines the distribution of 179 species nesting within Vermont. Each species account has a map with breeding locations, descriptive text, a drawing of each bird, and historical distribution data. *Published for the Vermont Institute of Natural Science.* 8 vinyl map overlays. £45.00/\$54.00

BOGS OF THE NORTHEAST

CHARLES W. JOHNSON

A generously illustrated book that presents many intriguing facets of bogs—unusual plants, intricate ecological relationships, animals, folklore, and the myriad history recorded in U.S. peats. It is the first popular book on bogs that is both comprehensive and authoritative. 37 photos (4 color plates). 41 line drawings. £12.95/\$15.50 paper, £25.00/\$30.00 cloth

Allen & Unwin[®] NEW TITLES

A PRACTICAL INTRODUCTION TO OPTICAL MINERALOGY

C.D. Gribble, *University of Glasgow*
A.J. Hall, *Strathclyde University*

Incorporating both transmitted-light and reflected-light microscopy, this introductory book provides the student with a first stepping-stone to the study of optical mineralogy. With dual-purpose microscopes being readily available and reflected light microscopy becoming increasingly important in undergraduate courses on ore mineralization and in the systematic petrographic study of rocks, coverage of both fields is now appropriate at the introductory level. The book is intended to aid identification of mineral relationships. As such, it will be useful to the undergraduate student beginning a course in optical mineralogy and also to the microscopist experienced in transmitted-light who needs an introduction to reflected-light technique.

Plenum: Keeping Pace with New Developments

HEALTH PSYCHOLOGY

A Psychobiological Perspective

by Michael Feuerstein, Elise E. Labbé, and Andrzej R. Kuczmierczyk

A balanced presentation of theoretical, empirical, and clinical aspects of the rapidly developing field of health psychology. Data from a number of subdisciplines within psychology and the behavioral and health sciences are integrated throughout the book to provide a clear picture of the contribution of the psychobiological approach to the understanding, treatment, and prevention of major health problems.

BIOLOGICAL RESPONSES IN CANCER

Volume 4

edited by Enrico Mihich

This series provides information on approaches through which the interaction between neoplastic and normal cells may be modified. Volume 4 is specifically concerned with different aspects of cell interactions and regulation within heterogeneous tumor cell populations, and their role in tumor progression and metastasization.

0-306-42044-9/270 pp./ill./1985

\$49.50 (\$59.40/£47.03 outside US & Canada)

THE JOY OF SCIENCE

Excellence and Its Rewards

by Carl J. Sindermann

"An engaging picture of science as it really is."

—Grant Gross, National Science Foundation

"Delightful, insightful, witty."

—Cecil Reynolds, Texas A&M University

This book is an account of the men and women who may never get invited to late evening television talk shows or nominated for a Nobel prize, but who are making significant contributions to science.

A Research Journal
Devoted to the
History of Science and
Its Cultural Influences

The History of Science Society is proud to announce a new series of *Osiris*. Columbia University's Robert K. Merton, whose pathbreaking "Science, Society, and Religion in Seventeenth Century England" was published in the first series of *Osiris*, calls the new series, "a must for every research library and every serious student of the history of science."

Edited by Arnold Thackray, *Osiris* will present major themes and research of wide interest to the history of science community.

VOLUME 1: *Historical Writing on American Science*. Guest-edited by Sally Gregory Kohlstedt and Margaret Rossiter. Fifteen essays survey the major concepts, disciplines, institutions, and policies of American science.

VOLUME 2: Authoritative monographs by major scholars including Garland E. Allen (on the Eugenics Record Office), David C. Lindberg (on Kepler's optics and the Neoplatonic tradition), Ernst Mayr (on J. G. Kolreuter's contribution to biology), James Reardon-Anderson (on chemical industry in China), and Susan Wright (on recombinant DNA technology).

Towards a New World synthesis

Colin A. Russell

Chemistry in America, 1876–1976. By Arnold Thackray, Jeffrey L. Sturchio, P. Thomas Carroll and Robert Bud. Reidel: 1985. Pp.564. Dfl.210, \$79.50, £53.50.

A CASUAL reader who decides to browse through this volume is in for quite a surprise. From the title one might expect an account of American chemistry (here meaning chemistry in the United States) on the lines of those engaging and once-popular series "a hundred years of this or that": bland, popular, anecdotal, synoptic, well-illustrated, easy on the eye and reasonably analytical. For the price and size one might expect all this on a lavish scale. Should our browser dally even for a moment at the title page he will, however, receive the first hint of unpredictability. The subtitle "historical indicators" suggests uncharted seas ahead. For, if these are not to do with the litmus-type indicators familiar to all chemists, what on earth are they? The confusion is not resolved by the apparently perverse and deliberate appropriation of the very phrase "chemical indicators" that has for so long had a quite precise if pedestrian connotation of an entirely different kind.

"Indicators", as used by these authors, are long-running trends in a series of statistical data. They are measurements of change. If, for example, you analyse census and other information about the employment of chemists in the United States, you find for the past century or so an annual growth rate of about five per cent in the chemical work-force, and that chemists have increased from 2 to 15 per 10,000 of the total numbers employed in any work. On the other hand, the proportion of high school chemical students who later specialize in chemistry has declined steadily, as has the esteem accorded to chemistry in public opinion surveys and its coverage in newspapers. And since about 1910 there has been absolute growth *but relative decline* in the place of chemistry in the internal economy of American universities.

In six chapters, occupying less than half the book, the authors present a profusion of tables, graphs, bar-charts and the like to show how American chemistry has changed in the context of industry, education and its professional organization. Their conclusions are helpfully summarized in each chapter by a few "indicator highlights". For people who are prepared to take the arguments on trust these brief conclusions are probably all that matter: two or three pages of print altogether. However with typical trans-Atlantic thoroughness the authors will not allow

us off the hook so easily. They parade their hard-won information in a spirit of modesty and self-criticism, and delight in warning of the hazards and limitations of their approach. As if to hammer the point home they append to the book over 200 pages of tables, some appendices on methodology and a bibliography of massive proportions.

The methods, like the idea of "indicators", derive from the social sciences. So also, apparently, does the phraseology, though this is mainly evident when the authors are being self-consciously coy about their strategy. Indeed it seems that the most avid users of the book are likely to be those students of society for whom chemistry is but another manifestation of social conditioning and manipulation. Such enquirers will find a wealth of raw material brought together for the first time, and also many hints and ideas for future research. Yet it is as part of a series devoted to the history of chemistry that this book appears, so it is not unreasonable to enquire what chemists and historians of science might make of it.

Chemical readers will here find little of the *content* of their science, even historically treated. They will, however, discover a great deal about its *context*, in which only the most myopic benchworker will be altogether uninterested. The conclusions, at least for American chemists, are not wholly agreeable, for the subject's decline is remorselessly depicted in the many graphs and tables. For those who plan and teach, these trends, however depressing, cannot now be ignored. If, as the authors claim, "chemical education begins to look like a sieve, leaking credentialed chemists in all directions", one would have thought that those who advise American youth would at least be glad to know. So, one imagines, would those responsible for science policy.

For historians of chemistry, the book will have little appeal to those who like their history warm, human, personalized and cosy. Nor will it be of much use to their polar opposites, historians of scientific ideas, philosophies and techniques. People to whom quantitative historical science is a contradiction in terms ("history by numbers" such efforts are contemptuously called) will look elsewhere for inspiration. Nor must the sceptics be dismissed as mere backwoodsmen. They have a real point when they urge that huge compilations of statistics either prove what you want them to prove (just select the right parameters) or that they merely clothe the blindingly obvious with pseudo-quantitative respectability. It is to the great credit of the authors of this book that they are well aware of these dangers, and do not attempt to conceal them and can (in a couple of apposite cartoons) even laugh at themselves.

Those whose interests lie in the so-called social history of science will find in *Chemistry in America* a fund of good ideas

and useful information, especially if they are concerned with institutions or education. Yet the book also has drawbacks for such people. The material relates to only one country — though admittedly a world leader in chemical research — and one is bound to seek comparisons with Britain, Germany and other countries if only for the earlier part of the period under consideration. Moreover, it is important that not only should national trends be compared but that allowance be made for different meanings for the variables measured. Thus the criterion of professionalization in chemistry is a very American one and different from that in Britain where the phenomenon first arose. Similar caution must be given about the definition of various classes of chemists which mean different things in different countries. "assayer" is a case in point.

It is not difficult to criticize the selection and presentation of the data. One looks in vain for information on such topical issues as the changing role and numbers of women in chemistry, the relation between chemistry and war, and even the question of chemists' salaries. In education, trends in chemistry are compared with those in history rather than in physics and biology. Again, there are surely more important issues to record than the number of ex-chemists who become deans in American universities or the ages (high) of Presidents of the American Chemical Society. However, the prominence given to that specific institution is one of the particularly creditable features of a book that is always in danger of submersion in an ocean of generalities.

In reading the book I became gradually conscious of a sense of *déjà vu*. Somewhere I had met something very like it before, but where? The impression crystallized into recognition by about Chapter 3. Its predecessor was nothing less than the massive *History of Chemistry* by J. R. Partington, published by Macmillan in four volumes between 1961 and 1970. Superficially the two works are light-years apart yet fundamentally they are doing the same thing: presenting a highly idiosyncratic view of a mountain of information with little or no attempt to digest it into a coherent, readable overview of the subject. Here, perhaps, is a Partington of a new era, with all the weaknesses and strengths of the original. Indigestible it may be, and one could certainly not read it from cover to cover. But if it turns out to be half as useful as Partington in supplying raw information and in catalysing future work, it will earn the gratitude of generations to come. Whether the trends it heralds in chemical history — empirical, pragmatic and semi-quantitative — will prove to be fruitful, time alone will tell. □

Space shuttles

Peter Kemp

Contact: A Novel. By Carl Sagan. *Simon & Schuster: 1985. Pp.432. \$18.95.*

AMONG the numerous — and often numinous — quotations strewn around Carl Sagan's latest novel, is Einstein's claim that "the cosmic religious feeling is the strongest and noblest motive for scientific research". True to this belief, Sagan's saga of galactic exploration keeps juxtaposing the scriptural and the scientific: apocalyptic sects and astronomers, angels and astronauts, messiahs and supernovae, tales of mystic experience and talk of transcendental numbers. Even in shape — opening with genesis and ending with revelation — his book seems to have its eye on the Bible.

The first page records the birth of Ellie, a baby who comes into the world with a look of "puzzlement". As she grows up, this matures into intellectual curiosity — especially about possible extraterrestrial life. Finding her vocation as a radioastronomer, Ellie pioneers new techniques for scanning the heavens — and, as the second millennium approaches, her hunch that there are powerful beings out there proves justified. From the vicinity of Vega, a coded communiqué is picked up, transmitting instructions for the manufacture of a massive machine. Despite objections from some quarters that this is a snare of Antichrist, construction work goes ahead. At last — on 31 December, 1999 — Ellie and four international colleagues board what has turned out to be a spaceship ready for launching.

Up to this point, Sagan's story has kept to fairly well-trodden ground, such as the way space research might foster "transnational" thinking and global unity: a notion regularly mooted in science fiction since the days of H. G. Wells. The crucial test for space travel stories, though, is what happens when their characters zoom away from Earth. After take-off, the narrative is at maximum risk of nose-diving into the banal.

This is a hazard Sagan doesn't altogether steer his way around. Though he musters an imposing array of technical terminology — as his crew shuttle through space, they exchange arcane remarks about "time-like Killing vectors, non-Abelian gauge invariance, geodesic refocusing, eleven-dimensional Kaluza-Klein treatments of supergravity" and the like — he also employs analogies that seem something of a let-down. The mysterious black tunnels along which his starcraft is whisked are, it is improbably suggested, like "a subway"; star systems loom up like stops along the line; the gigantic junction at the heart of it all is "Grand Central Station".

Even more surprisingly down-to-earth

is the destination at which his travellers disembark: a kind of far-fetched Disneyland. Alighting on a simulation of a tropical beach — all palm trees and balmy breezes — they are greeted by aliens who have considerably assumed not merely human shape but that of their guests' "deepest loves". More suggestive of *When You Wish Upon A Star* than of what you might expect to find when you travel to one, these sentimental look-alikes are also designed, it appears, to figure as equivalents of scriptural divinities: "beings who live in the sky, beings enormously knowledgeable and powerful, beings concerned for our survival". "How . . . theological

. . . the circumstances had become". Ellie reflects excitedly. But, for all the book's strainings towards some loftily spiritual sphere, its final message is mundane. Returned to Earth after her galactic gallivantings, Ellie clutches the insight that "For small creatures such as we the vastness is bearable only through love". A piece of enlightenment you'd hardly think it necessary to travel light-years to acquire, it's disappointingly typical of the way this story tends to drop from the nebular to the nebulous. □

A light on the past

Hendrik B.G. Casimir

History of Physics: Readings from Physics Today. Edited by Spencer R. Weart and Melba Phillips. *American Institute of Physics: 1985. Pp.375. Pbk \$25.*

WHEN, in 1948, the American Institute of Physics (AIP) launched *Physics Today*, it did not intend the journal to deal with the past. The new publication addressed itself to members of the AIP and of its several affiliated bodies, and aimed at keeping them informed about what was happening in physics, both from a scientific and from an institutional point of view. Only in 1952 did a contribution of a historical, or at least of a retrospective character appear in its columns, but from then on historical articles became a more or less regular feature. *History of Physics* — a somewhat grandiose title which is put into proportion by the inconspicuously printed subtitle, *Readings from Physics Today* — is an anthology of such articles, together with a brief introduction.

The introduction gives a useful survey of the activities of the AIP in the field of history and of the development of other such work in the United States since the Second World War. In another respect, however, it is not entirely satisfactory; when the editors state that there was hard-

ly any organized research into the subject before 1950 — that there were no books, no papers, no journals on the history of physics — they are taking a rather parochial view. On this side of the Atlantic we had E.T. Whittaker's great work *History of the Theories of Aether and Electricity* and the famous *Ostwald's Klassiker*, annotated reprints of important papers, to name but two examples. Moreover there were many biographies and autobiographies, and several journals dealing partly or entirely with the history of science, including physics.

This, however, is a point of minor importance and should not deter prospective readers. What really matters is the selection of material and in this respect the editors have done an excellent job. Not surprisingly, the articles differ widely in style and in scope, which makes it difficult to characterize the book as a whole. The best I can do is to discuss a few typical examples.

Two papers, one by Goudsmit and one by Uhlenbeck, deal with the birth of the notion of the spinning electron and with the circumstances that surrounded it. Here we have the story of a seminal idea, related by the originators half a century later. In consequence not only do these essays give a vivid impression of quantum physics and spectroscopy in the 1920s, and of the little group working with Ehrenfest at Leiden University, but they also provide an intriguing insight into the later

Spinning Electrons and the Structure of Spectra.

So far as we know, the idea of a quantised spinning of the electron was put forward for the first time by A. K. Compton (*Journ. Frankl. Inst.*, Aug. 1921, p. 145), who pointed out the possible bearing of this idea on the origin of the natural unit of magnetism. Without being aware of Compton's suggestion, we have directed attention in a recent note (*Naturwissenschaften*, Nov. 20, 1923) to the possibility of applying the spinning electron to interpret a number of features of the quantum theory of the Zeeman effect, which were brought to light by the work

of this moment of momentum is given by $Kh \cdot 2\pi$, where $K = \frac{1}{2}, 1, \frac{3}{2}, 2, \dots$. The total angular momentum of the atom is $Jh \cdot 2\pi$, where $J = 1, 2, 3, \dots$. The symbols K and J correspond to those used by Landé in his classification of the Zeeman effects of the optical multiplets. The letters S, P, D also relate to the analogy with the structure of optical spectra which we consider below. The dotted lines represent the position of the energy levels to be expected in the absence of the spin of the electron. As the arrows indicate, this spin now splits each level into two, with the exception of the level $K = \frac{1}{2}$, which is only displaced.

In order to account for the experimental facts, the resulting levels must fall in just the same places as the levels given by the older theory. Nevertheless, the two schemes differ fundamentally. In particular, the new theory explains at once the occurrence of certain components in the fine structure of the hydrogen spectrum and of the helium spark spectrum

NEW TITLES IN THE BIOSCIENCES

Research Notes in the Biosciences **Hormone Binding Sites in Plants**

By Michael Venis

The first set of research notes to be devoted to receptors for plant growth hormones. Essential for plant scientists, cell scientists and biochemists.

October 1985 / ISBN 0 582 07800 8 / 191pp / £15.00

Monographs and Surveys in the **Biosciences Experimental** **Manipulation of Ovule Tissues**

Edited by G P Chapman, S H Mantell and R W Daniels

Much of the work is previously unpublished in particular developments in micromanipulation, and modifications on DNA supplied to ovules.

September 1985 / ISBN 0 582 07801 6 / 256pp / £35.00

COMING SOON:

Carrier-mediated Transport of Solutes **from Blood to Tissue**

Edited by D L Yudilevich and G E Mann

Current research into the mechanisms regulating membrane transport and/or receptor events at the blood-tissue interface of intact organs.

December 1985 / ISBN 0 582 07802 4 / 448pp / £35.00

LES EDITIONS INSERM

NEW SERIES « RESEARCH IN... »

Editions INSERM/John Libbey Eurotext ⁽¹⁾

Published simultaneously in French and English versions, this new « Research In » series encompasses all the fields of biomedical and health research in which French research and INSERM in particular holds a privileged international position.

Isolated and cultured hepatocytes

A. Guillouzo et Ch. Guguen - Guillouzo

This work of reference will be useful to hepatologists, gastroenterologists, researchers interested in the hepatocyte, to cellular and molecular biologists and to graduate students.

Hardback, 500 pages, 1985

£ 35,00 - US \$ 62,00 - FF 450

SERIES « GRANDES ENQUETES »

Editions INSERM/DOIN ⁽²⁾

Naître en France

C. Rumeau-Rouquette, C. du Mazaubrun, Y. Rabarison

Three national studies conducted on the basis of representative birth samples for the entire french territory allow to estimate the evolution of perinatal morbidity as well as its prevention during the last ten years.

1984, 240 pages - US \$ 20 - FF 110

Mortalité des jeunes dans la Communauté européenne (de la naissance à 24 ans)

M. Kaminski, M.H. Bouvier-Colle, B. Blondel

This publication is based on mortality data from birth to the age of 24 years, analysed by sex and cause within the ten member states of the European Community from 1960 to 1980. The main objective of this study is the critical analysis of these mortality statistics and the comparison of the level of mortality and causes of death for various age-groups.

1985, 332 pages - US \$ 30 - FF 210

SYMPOSIA

Spinal opioids of the relief of pain

J.M. Besson, Y. Lazorthes

This volume brings together studies presented at a multidisciplinary international symposium by both basic scientists and clinicians. The first part of the volume covers fundamental aspects. The second part is concerned with the clinical treatment of chronic pain in man. The most important application of this therapeutic approach is to the pain of cancer.

1985 - Vol. 127 - 520 pages - US \$ 25 - FF 187,25

views of two senior scientists.

A delightful curiosity is the text of an address given by Einstein at Kyoto University on 14 December 1922, "How I Created the Theory of Relativity". The lecture was given in German and a Japanese physicist, J. Ishiwara, provided a translation. In 1923 Ishiwara published his Japanese text and in 1982 *Physics Today* printed an English translation by Yoshimasa A. Ono. Clearly, knowing that the lecture was to be translated, Einstein had formulated his ideas as concisely and simply as possible, but even so it is remarkable to see how well the text has survived two consecutive translations. There are several other articles in which the story of an important discovery or invention is told by people who were not necessarily the only originators but who did play an important part — Frisch and Wheeler on the discovery of fission is a good example, as is the history of the cyclotron told by Livingston and McMillan.

Also included are several biographical essays. Most of these are written by authors who were well-acquainted with their subjects, as their students or collaborators, which makes the stories lively and readable — here, Oliphant's "The Two Ernests" (Rutherford and Lawrence) is especially illuminating. Quite different again are the scholarly papers on specific aspects of the history of physics, for example Martin Klein's thorough study "Thermodynamics and Quanta in Planck's Work". Klein shows how Planck, a conservative rather than a revolutionary, found it hard to reconcile himself to his own innovation, but finally arrived at the conclusion "that the quantum of action played a far more significant part in physics than I had originally been inclined to suspect".

It is understandable that the contributions on institutional history deal almost exclusively with American establishments, and the same is true, though to a lesser extent, of the articles grouped under the heading "Social Context". But this does not mean that they are of no interest to non-Americans, and in many cases the problems discussed are international in nature. Of particular interest here is the article by Vera Kistiakowski with the provocative title "Women in Physics: Unnecessary, Injurious and Out of Place?"

Few people will read this book from cover to cover — the editors even warn against trying to do this. But all physicists and many non-physicists will enjoy leafing through it, will admire the many excellent illustrations, and will sooner or later start reading in earnest. □

Hendrik B.G. Casimir, *De Zegge 7 5591 TT Heeze, The Netherlands, studied theoretical physics at Leiden, Copenhagen and Zürich during the 1920s and 1930s and later became joint director of research at the Philips Company, Eindhoven. His autobiography, Haphazard Reality: Half a Century of Science, was published by Harper & Row in 1983.*

In the realm of the cosmocrats

Edward Harrison

The Cosmological Distance Ladder: Distance and Time in the Universe. By Michael Rowan-Robinson. W.H. Freeman: 1985. Pp.353. \$35.95, £19.95.

COMTE de Buffon once said that the forms of life seem more like chain mail than a Great Chain of Being. Similarly the measure of the universe seems more like a network of ladders than a single cosmological distance ladder. (An irreverent person might say more like a game of snakes and ladders.)

The scale of the universe has been increased several times since Hubble wrote *The Realm of the Nebulae* in 1936. The Hubble term H in the velocity-distance law (velocity = $H \times$ distance) has decreased in value by an order of magnitude and now stands at either 100 or 50 km s⁻¹ Mpc⁻¹. The de Vaucouleurs school champions the higher value and the Sandage-Tammann school the lower value. The reciprocal of H is about fifteen thousand million years and serves as a rough measure of the age of the universe.

Rowan-Robinson unifies his splendid and comprehensive survey of the universe — planets, stars, star clusters, galaxies, galaxy clusters, superclusters — with the theme of the cosmological distance ladder. In the preface he writes that, at a conference in 1976,

Gerard de Vaucouleurs on the one hand, and Allan Sandage and Gustav Tammann on the other, arrived at estimates of the size of the universe, as measured by the Hubble constant, differing from each other by a factor or two. Moreover, when I asked the protagonists what was the range outside which they could not imagine the Hubble constant lying, these ranges did not even overlap. . . . It was to understand this disagreement that I set out to write this book.

Using numerous figures, tables and appendices that display a wealth of data, the author builds an array of distance indicators and presents a difficult subject in a methodical manner. Skilfully he adjusts, deftly weighs, and adroitly averages divergent results.

The first rung on the ladder is the distance between the Sun and the Earth. Then comes the distance to the Hyades, the nearest open star cluster, determined by parallax and moving cluster methods. The size of this preliminary and important step, now estimated to be 150 light-years, has grown 30 per cent since 1940.

We measure in Hyades-units the distance to other open clusters, applying various methods including evolutionary curve fitting. Then, with allowance for absorption of light by interstellar dust, we use Cepheids and RR Lyrae variable stars as yardsticks to gauge the distances of globular clusters in our Galaxy and of nearby galaxies in the Local Group (rival schools going different ways and making different allowances for extinction of light). Novae, supernovae and HII regions, adjusted for extinction in the observed galaxy, serve as intergalactic

indicators of distance; here the methods become less reliable and the uncertainties increase yet further. Supergiant galaxies then act as stepping stones to remoter regions.

It began with the Greeks. Rowan-Robinson gives them a page or two and then jumps, as one expects in an astronomer's history of astronomy, from Aristotle to Copernicus. The Epicurean system (an infinite atomic universe) and Stoic system (an island cosmos surrounded by an infinite extracosmic void) receive scant attention, although both dominated the intellectual climate of the ancient world. The great historical drama of the mediaeval revival of the Aristotelian system, the eclipse of this system in the late Middle Ages by a nascent Stoic system, the rebirth of the Epicurean system, and the eventual overthrow of the Stoic system in the Great Debate of the 1920s also receives little recognition. We are told that in the seventeenth century Cassini measured the Sun–Earth distance to within 10 per cent of the modern value, but not that Newton, by using James Gregory's photometric method of comparing the outer planets with the brightest stars, determined with astounding accuracy (within a factor of two for Sirius) the distance of the nearest stars.

In a chapter entitled "The Cosmological Models", which is devoted to theoretical topics, the author discusses dynamic models, redshifts, proper and luminosity distances, the early universe, and the motion of the Solar System relative to the microwave background and to the Local Supercluster. Perhaps more such analysis in the other chapters would have helped the reader to surmount the mountains of data to be found in them.

The axioms or irreducible assumptions of modern cosmology rarely receive adequate attention, and the book would have benefited from some discussion of these hidden assumptions. The Hubble (and deceleration) term tell us how the universe expands. But how exactly do we need to know its value? Theorists first postulated the velocity–distance law, which applies at any instant throughout a homogeneous expanding universe. But when we look out in space we also look back in time, and homogeneity (unlike isotropy) cannot be directly seen. Observations made on the backward light cone are adjusted for evolutionary effects and mapped in a hypothetical homogeneous space. At best we verify that redshifts and estimated distances are consistent within the theoretical frame of a geometric and dynamic model that is itself unverified. Perhaps our models are too simple and we do not know enough cosmology to make an exact value of the Hubble term meaningful? □

Edward Harrison is Professor of Astronomy in the Department of Physics and Astronomy, University of Massachusetts, Amherst, Massachusetts 01003, USA.

Halley's comet in print

David W Hughes

ON 16 October 1982 Halley's comet was picked up using a charge-coupled device at the prime focus of the 5.1 m Hale telescope on Mount Palomar. It has been monitored ever since. As it approaches the Sun it brightens and will become just visible to the naked eye between December 1985 and April 1986. But there are two problems for observers. On 9 February 1986 the comet is at its closest to the Sun and for a six-week period around then is in too bright a region of sky to be easily visible. Also, between December and April it sweeps from the northern to the southern sky, requiring the northern observer to reciprocate by moving to the southern hemisphere. Unfortunately planet Earth does not get very close to the comet this time, so we are not going to be overawed by startling searchlight-like beams radiating up from the twilight horizon. In fact the mere act of catching sight of the comet will require some effort.

Halley's return to the inner Solar System has been greeted by a whirlwind of books, and thus a rather rare state of affairs as far as the reviewer is concerned. Most of them in fact say much the same things, use the same illustrations and are aimed at a like audience. Most are written by non-specialists who, for simplicity, have consulted only secondary sources of information and have consequently made many mistakes. Reviewing them is akin to essay-marking. To help the prospective buyer the books are divided into categories, with a star rating for each according to whether it is thought to be excellent, good, indifferent or poor. The five-star rating is reserved for those rare books in the pile that will "last", to be consulted around AD 2061 when Halley's comet returns once more.

The categories are as follows: (i) Books specifically designed to help the reader see the comet (the message being that you have a once-in-a-lifetime chance so make the most of it); (ii) guides for teachers, that is books specifically designed for the organizers of classes; (iii) specialist books; and (iv) general books.

Halley's Comet by Francis Reddy leads the first category. It abounds with good advice: "If you want to see the comet you had better prepare for it, familiarize yourself with the constellations through which Halley moves, get away from cities, use your binoculars and travel south". Twenty maps are provided, for three Earth latitudes (55°N, 40°N and 35°S). These not only show the comet and its tail against the starry background but also include (where appropriate) the Moon, Mars and Jupiter. A superb three-dimensional model of the orbits of the comet and Earth is an additional bonus.

Such models are a great help when it

comes to visualizing the movement of the comet with respect to the Sun and Earth, and Perihelion Scientific have produced one, *Halley's Comet Survival Kit*, which is 85 cm across. Another accompanying model enables you to calculate the altitude and azimuth of the comet throughout the November 1985–May 1986 period. Both are great fun to assemble and use.

If you are happier with a planisphere, David Chandler has designed a set of three (for northern latitudes 26°, 35° and 44°). These show the comet's path through the constellations and it is simplicity itself to calculate when and where it can be seen. Unfortunately there are no hints as to its brightness.

Halley's Comet Finder by Ben Mayer is aimed more at the astronomically initiated and gives a detailed review of the comet's journey across the sky. The section on astrophotography in this book is most useful.

For the complete beginner the editors of *Sky and Telescope* have produced *Mr. Halley's Comet* (I've no idea why they refer to a man who was an eminent professor and had two doctorates as "Mr."). This is an excellent and inexpensive guide marred only by the sparsity of stars on the sky map. The fact that a pair of binoculars has only a limited field of view is rightly stressed, but the difficulty of finding the comet and recognizing stars in the field is somewhat overlooked. The guide seems to be designed in the hope that the comet would be much brighter.

Moving into the classroom, both *Comet Halley Returns* and *Halley's Comet Activities Manual* get good marks and will provide science teachers and their scholars with hours of activity understanding comets, modelling their orbits, recording observations, computing examples of Keplerian motion, introducing the life and times of Edmond Halley and trying to appreciate his achievement. *Halley's Comet: Teacher's Notes* comes with posters and is biased towards young (9–14) or innumerate pupils (and supposedly innumerate teachers too!). It approaches cometary science from a sociological and refreshingly critical standpoint — I'm still considering "the possibility that women astronomers do not appear in astronomy books because those books are generally written by men", one of the topics suggested for classroom discussion. Mary Ashby, the author, has a clear grasp of what children find interesting and what they find difficult to understand, and has planned a series of exercises for explaining difficult concepts.

Nine books fall into the specialist category, two of which are bibliographies. Ruth S. Freitag lists 3,289 references to both popular and scientific cometary literature. The list is alphabetical by author and each

reference is followed by a short description of the item. This book is an indispensable source for anyone seeking data on the comet's previous apparitions, technical literature on the Halley spacecraft missions or manifestations of popular interest in comets. Just turn to the index, and look up, for example, "Essays and sketches, humorous"; "fiction"; "recovery (1759)"; "transits across the sun's disk"; "music"; and "mass spectroscopy". What a godsend this book is. I hope that Ruth Freitag can be persuaded to bring the work up to date in, say, 1990 when the present hullabaloo has died down.

Bruce Morton's bibliography will be less useful because he has deliberately omitted all non-English language source material. The listing is chronological but is backed up with an author and subject index. Morton only lists 1,301 items but does include many not covered by Freitag. Researchers will need both books.

Fire and Ice by Roberta J.M. Olson is an art historian's view of comets and has been published to accompany an exhibition of comets in art at the National Air and Space Museum in Washington, DC. The main attraction of Olson's book is the art reproductions. There are over a hundred pictures of comets, many in colour. Rackham, Moreau, Turner, Gérard, Blake, Daumier, van Stolk, Stech, Scott, Giotto — the list of artists is impressive. The text serves two purposes, first, to introduce the pictures and fit them into the context of the history of art, and secondly to weave in the development of man's fear and understanding of comets as shown in the paintings, engravings and illustrations of the day. All this is both entertaining and enlightening, but let me mention two minor quibbles. If someone has gone to the trouble to paint "Dr Halley" across the top of the Phillips portrait of our hero, why entitle it "Sir Edmund Halley" in the book? He wasn't knighted and he spelt his christian name *Edmond*. Also it must be remembered that Halley's comet was not *that* famous before 1705. Giotto might not have had to remember the comet of 1301; he might have popped out in December 1304 and painted the long-period comet that was in the sky then.

Peter Lancaster-Brown in *Halley and his Comet* has concentrated on the non-artistic historical aspects of the story, and creatively charts the transition of comets from astrological portents (in pre-Halleyan times) to their present status as unusual astronomical objects. The author has produced a most readable book, but one in which he has not resisted the temptation to fill in some of the gaps: lines such as "We might surmise without stretching credulity . . ." often end in rather too imaginative conjecture. If Newton was a latent homosexual, and Halley a philanderer, I would like chapter and verse.

All serious cometary historians should get a copy of *La Comète de Halley: Hier,*

Aujourd'hui, Demain by J. Alexandre and S. Debarbat. This is a small folder containing a collection of reproductions of Halley comet documents from the Paris Observatory. The Lubientietz maps and the drawings by Hevelius, Arnold, La Hire, J.-D. Cassini and Schwabe are fascinating, while Messier's hand-written account of the 1758 apparition is in the first division of historic documents.

Comet Fever by Donald Gropman has as its main theme the 1910 appearance of the comet and especially the dramatic events of the night of 18–19 May when the Earth swept through the comet's tail. We are told of sealed windows, absenteeism from home and work, mass prayer ses-

Richard Phillip's portrait of Halley circa 1721.

sions and, to cap it all, all the news fit to print about the infamous Oklahoma 19-year-old-naked-virgin-sacrifice-drama. Other chapters skim over past apparitions of Halley and aspects of modern cometary science, making in all a well-written, extremely readable book.

Fred L. Whipple is the doyen of comet scientists having worked extremely profitably in the field of cometary astronomy for 50 years. What he has to say about comets is certainly worth reading and his book, *The Mystery of Comets*, is superb. Too few scientists take the time to explain the complexities of their subject to a general audience. Whipple has left nothing out — if you want a synopsis of what is known about comets and, even more exciting, what is still beyond our present grasp, this is the book for you.

Another book that will be consulted for decades is *Halley's Comet in History*, edited by F.R. Stephenson and C.B.F. Walker, which emphasizes the Babylonian and Chinese records of the comet between 240 BC and AD 1531. The 13-page, line-by-line translation of a 164 BC Babylonian cuneiform tablet is rather strong meat for the casual browser, but if you need the historical information this is where to look. I wish more than one figure showing the comet's path across the sky had been included — the book would have been greatly enhanced by including a set of these for the relevant 23 apparitions.

Comet by Carl Sagan and Ann Druyan is a visual and intellectual feast, combining a host of specially commissioned colour illustrations with a text that, for the breadth of insight into the past, present

and future of cometary science, is way ahead of the rest of the field.

Standing back from all the razzamatazz surrounding this apparition, the book concentrates on the fundamentals: why have comets worried people, what have scientists and philosophers made of them, what is their origin, composition and fate? The Sagans' inquisitive enthusiasm is infectious. Sometimes they approach that danger zone where the gap between fact and speculation is overlooked, but they are soon forgiven. For me, comets will never be the same again. Cometary science can only blossom with such champions.

Finally, to the general books — those containing a bit of everything, history, comet lore and an observer's guide. Confronted with eight of them the reviewer is forced to list them in order of preference, a difficult task because they all have "curate's egg" properties. First past the post is Patrick Moore and John Mason's *The Return of Halley's Comet*. The maps are excellent, giving you a real chance of spotting the comet, and the review of comet science and decay is impressive. Make sure you get the new edition.

Close behind are Brian Harpur's *The Official Halley's Comet Book* and Mark Littmann and Donald K. Yeomans's *Comet Halley: Once in a Lifetime*. Both are superbly illustrated and overflowing with anecdotes. Harpur's review of cometary poetry and literature is masterly, while Littmann and Yeomans put across the scientific message superbly. With both, however, you will need additional help to find the comet.

In much the same category we find *A Comet Called Halley* by Ian Ridpath and Terence Murtagh. The text is excellent but some of the illustrations are a touch odd; surely the *Vega* spacecraft doesn't look like that! And it would be much easier to find the comet if it was shown with respect to compass points and elevation, and not just vaguely trundling across the constellations.

Occupying the uninspiring section where the errors proliferate and the illustrations become even more blurred we find four books by Richard Flaste *et al.*, John Tullius, Donald Tattersfield and Isaac Asimov. Reading these convinces me that there are many better ways of spending one's time and money.

The entire collection (which, incidentally, is by no means a comprehensive display of Halleyana) is listed in the table on the following page. But, to summarize: if you want to see Halley's comet read Francis Reddy; if you want to stay in your armchair with your feet up, read Brian Harpur, and Sagan and Druyan; if you want to know about comets in general you can do no better than Fred Whipple; and if you want to find something out for yourself get Ruth Freitag's bibliography. [.]

David W. Hughes is Senior Lecturer in Astronomy and Physics, Department of Physics, University of Sheffield, Sheffield S3 7RH.

Halley's comet in print — details of the publications

Title	Author/editor	Publisher	Pp.	Price	Rating
Seeing the comet					
Halley's Comet	Francis Reddy	AstroMedia, Milwaukee, WI/Pan, London	59	Pbk \$9.95, £7.95	*****
Halley's Comet Survival Kit	Tom Gaffney <i>et al.</i>	Perihelion Scientific, Paoli, PA	—	North America \$14.95; elsewhere \$20.25	**

Recent progress and future plans on the search for extraterrestrial intelligence

Michael D. Papagiannis

Department of Astronomy, Boston University, Boston, Massachusetts 02215, USA

The possibility of life in other parts of the Universe has long occupied the human mind, but actual searches only began in 1960 with Project OZMA conducted by Frank Drake. In the past 25 years, we have made impressive progress, and this new field has gained broad scientific recognition including the support of the US and the Soviet National Academies, and the endorsement of the International Astronomical Union.

PEOPLE have been fascinated by the possibility of intelligent life in other parts of the Universe for at least 2,500 yr (refs 1, 2). Around 400 BC, for example, the Greek philosopher Metrodorus of Chios wrote³: "It seems impossible in a large field to have only one shaft of wheat and in the infinite Universe only one living world." The question, however, remained a philosophical one until the middle of this century, when Cocconi and Morrison⁴ urged the scientific community to undertake radio searches in the vicinity of the 21-cm line of atomic hydrogen, the only radioastronomical line known at the time, for radio messages from other civilizations. They closed their paper with the statement: "The probability of success is difficult to estimate, but if we never search the chance of success is zero."

Independently, F. Drake, a young radioastronomer in the then embryonic staff of the National Radio Astronomy Observatory (NRAO) at Green Bank, West Virginia, was planning to undertake such a search with the 85-ft Tatel radiotelescope, the only one then existing at Green Bank. The search was undertaken in the spring of 1960, logging 200 h of observations of two Sun-like nearby stars, Epsilon Eridani (10.7 light yr) and Tau Ceti (11.9 light yr). He used a single-channel receiver and a new parametric amplifier, the best then available, which allowed him to reduce the system temperature from 1,500 K to ~350 K. The project was named OZMA after the Princess of the mythical kingdom of Oz. Drake⁵ reports the excitement of a false alarm they experienced when they first tuned their antenna to Epsilon Eridani. Such heart-stoppers have not been uncommon in projects associated with the search for extraterrestrial intelligence (SETI).

After a rather slow start in the 1960s (only three searches in the first 7 yr with less than 300 h of observations), SETI began to gain momentum in the 1970s, thanks to a meeting at the Byurakan Observatory⁶ in Soviet Armenia which was co-sponsored by the National Academies of both the Soviet Union and the United States, and a series of design studies⁷, workshops^{8,9} and conferences¹⁰, organized by the National Aeronautics and Space Administration (NASA) at its Ames Research Center. Finally in the 1980s it became established as an active branch of both the life sciences (exobiology) and of astronomy (bioastronomy). SETI was also included in the recommended astronomy projects for the 1980s by a special committee of the US National Academy of Sciences¹¹ and gained the endorsement of the International Astronomical Union (IAU), which at its 1982 triennial General Assembly established a new Commission¹² on this subject (IAU Commission 51—Search for Extraterrestrial Life). I was elected president, and N. Kardashev of the Soviet Union and F. Drake of the United States vice-presidents, all for the period 1982–85. The new commission grew rapidly to about 270 members and in 18–21 June 1984 organized in Boston the first IAU Symposium¹³ of this new branch of astronomy, which is rapidly becoming known as bioastronomy. During this symposium we celebrated 25 years since the historic paper by Cocconi and Morrison, while in the

spring of 1985 we celebrated the 25th anniversary of Project OZMA with a special meeting at NRAO in Green Bank which was attended by Drake and many of the pioneers and current workers in this field.

Search projects

In these 25 yr there have been about 50 search projects, most of them at radio frequencies but a few also in the optical and in the infrared. J. Tarter¹⁴ maintains the only active file of all these projects, which I have used as the basis for most of the descriptions that follow, augmented by personal information and data from papers by the experimenters included in ref. 13. So far we have amassed close to 120,000 h of observations using facilities in seven countries (United States, Soviet Union, Australia, Canada, France, Germany and Holland). Japan¹⁵ is also preparing to join the group with its new 45-m Nobeyama millimetre radiotelescope which is equipped with two acousto-optical spectrometers, one with 16,384 channels and a 2-GHz total bandwidth, and the other with 8,192 channels and a 160-MHz total bandwidth. They also have a 4,096 Fourier transform spectrometer with a frequency resolution of 150 Hz–10 kHz.

Almost all of the radio searches up to now have been conducted at selected 'magic frequencies', because from knowledge of science these radio lines would be known both to the transmitting and to the listening civilizations. This idea was advanced by Cocconi and Morrison⁴ who in essence said that if indeed 'they' want to make contact with us, 'they' will make it as easy as possible by transmitting at a frequency that is universally known. At the time, the 21-cm hydrogen line was the only one we knew, and though we now know radio lines of more than 65 atoms, molecules and radicals, the hydrogen line (*primus inter pares*) continues to dominate the searches. Unfortunately this reasoning has not paid off, but there was nothing else we could have done with the technology then available. In the next generation of searches, however, we plan to use multichannel spectrum analysers (MCSAs) with many millions of channels to search over a wide frequency range, rather than focusing only on certain magic frequencies.

Below we review the different searches that have been undertaken in the past 7 yr, or that are in progress. Following Tarter¹⁴, we will divide them into three general categories: Directed, Shared or Parasitic, and Dedicated, which are differentiated by the use they make of their observing facilities. For a description of searches before 1978 see ref. 16.

Directed searches

These searches use a major observatory for a specific SETI project of relatively short duration. Thus, in 1978, Sullivan *et al.*¹⁷ of the University of Washington proposed that an alternative search strategy would be to eavesdrop on nearby stars for radio signals leaking unintentionally into space from other advanced civilizations. As a test, Sullivan and Knowles¹⁸ used the large Arecibo antenna to observe the radio leakage of the

Earth in the 150–500-MHz range from its reflections from the Moon. Strong television stations and powerful military radars are the most prominent sources. As an example, the space surveillance radar of the US Navy in Archer City, Texas, which operates at 217 MHz emitting pulses of 1.4×10^{10} W into a bandwidth of only 0.1 Hz, could have been detected by a civilization with an Arecibo technology to a distance of 20 light yr. Knowles¹⁹ and Sullivan also did a limited eavesdropping search on a few nearby stars. The data were obtained with the Arecibo radiotelescope and the Mark I VLBI (very-long-baseline interferometry) system. They were analyzed for ultra-narrowband signals over a wide frequency range using a computer to create large Fourier transforms from tape-recorded one-bit time histories of the telescope voltage output. This technique, 'one-bit spectral analysis', is no substitute for a large MCSA, but can be used in parallel utilizing otherwise idle computer time. Although this test-run found no signals, it showed that eavesdropping on nearby stars is an alternative search technique that must be explored further.

Other directed searches in the United States include those of Tarter, Clark, Cuzzi, Duquet and Lesyna who used the Arecibo radiotelescope to observe 210 solar-type stars in a 4-MHz band around the magic frequencies of both HI and OH, and who also used the one-bit tape-recording technology and a CDC 7,600 computer to obtain a spectral resolution of 5.5 Hz. Using the 14-m millimetre radiotelescope of the University of Massachusetts, Lord and O'Dea looked for powerful beacons at the 115-GHz (2.6-mm) line of CO along the north rotational axis of the Galaxy, a potentially 'magic location' for beacons operated by supercivilizations.

On the other side of the Atlantic, F. Biraud of the Observatory of Meudon and J. Tarter of Berkeley and NASA-Ames have been using the large (40 × 240 m) radiotelescope at Nançay, France, since 1981, and an eight-level 1,024-channel autocorrelator with a resolution of 50 Hz per channel to observe 300 solar-type stars at four OH frequencies. This project is complementing previous work done with the Arecibo and the 300-ft NRAO radiotelescopes, where low declination sources had not been observed. In Holland, Shostak of the Kapteyn Astronomical Institute and Tarter used in Project SIGNAL the Westerbork array to look with high angular resolution (to screen out noise) for a pulsed beacon, with a repetition rate between 40 s and 1 h, at the centre of the Galaxy, a magic location for a supercivilization.

P. Horowitz of Harvard, while on sabbatical at Stanford, built together with Teague, Linscott, Chen and Backus, an impressively compact MCSA, which they named 'Suitcase SETI'. It had 65,536 (2^{16}) channels for each of the two circular polarizations and a resolution of 0.03 Hz per channel. They used it in Arecibo to observe 250 solar-type stars at the hydrogen line and at twice the hydrogen frequency. They were looking for an ultra-narrowband signal, which is the most economic means for interstellar communications. The Drake-Helou spreading²⁰ due to multiple scattering from inhomogeneities of the interstellar medium, limits the narrowness of the signal to a bandwidth of 0.01–0.1 Hz. This initial experiment later led to Project SENTINEL. Another interesting search was undertaken in 1983 by R. Freitas and F. Valdez who used the Hat Creek radio observatory to conduct a search at the 1,516-MHz line of tritium. Since tritium has a half-life of only 12.5 yr, if found in the vicinity of normal stars it could only have an artificial origin, possibly the by-product of a huge nuclear fusion plant. The same workers had earlier used the 30-inch telescope of the University of California and the 24-inch telescope of the Kitt Peak National Observatory (KPNO) to conduct an optical search for artefacts and probes placed in our Solar System by extrasolar civilizations. They looked at the magic locations of the L4 and L5 Lagrange points of the Earth–Moon and Earth–Sun systems, which are the most stable regions in space to observe the Earth.

Other non-radio search projects include those of V. Shvartsman and his colleagues of the Special Astrophysical Observatory of the Soviet Union, who used the 6-m optical telescope at

Zelenchuskaya, USSR, and a device called MANIA which can detect very short pulses (3×10^{-7} – 3×10^2 s) from optical lasers, to look at 21 stellar objects with unusual spectral properties, hypothesizing that they may be examples of supercivilizations that could be using laser signals for interstellar communications. In a related project, a laser heterodyne receiver operating at 30 THz (10 μ m) is now being built by H. Betz of the University of California-Berkeley that will have 1,000 channels each 1 MHz wide, to undertake an infrared search for extraterrestrial laser signals which in certain circumstances might be used for interstellar communications. Finally, I²¹ am preparing to undertake a search for large artificial objects (such as space colonies and materials processing plants) in our Solar System and especially in the asteroid belt, which is an ideal source of raw materials, to test the theory of galactic colonization, that is, the possibility that the entire Galaxy might already have been colonized by more advanced civilizations. I will be using the Infrared Astronomy Satellite (IRAS) data bank of infrared sources in our Solar System, which is now being prepared at the Jet Propulsion Laboratory by the IRAS Asteroid Workshop²², to look for objects with unusual infrared signatures in our Solar System.

Shared or parasitic searches

These searches either re-analyse for ETI signals old, archived data that had been obtained for other purposes, or they share in a parasitic or piggyback fashion the data being obtained by a radiotelescope for an unrelated project and process them for ETI signals in real time. Thus by re-analysing many of the 21-cm 'noisy' sky maps that had been obtained with the Westerbork array and had been kept by the Dutch astronomers, F. Israel of the Netherlands working first with DeRuiter and then with Tarter, looked for strong sources in positions that coincided with those of known stars. It is hoped that a similar process will be used in the future with maps obtained with the VLA (Very Large Array). Meanwhile, Cohen *et al.*²³ re-analysed their own surveys of globular clusters, looking for narrowband signals at frequencies associated with OH and H₂O masers that might be tapped by supercivilizations to produce strong signals in certain directions. M. Damashek is re-analysing for ETI signals 700 h of data that he had obtained with the NRAO 300-ft antenna during an extensive pulsar search at 390 MHz over most of the sky.

In 1980, S. Bowyer and D. Werthimer of the University of California-Berkeley and their collaborators^{24,25}, built an automated 100-channel spectrum analyser to siphon through it, from the intermediate frequency (IF) stage, data obtained by a telescope for an unrelated project. This parasitic or piggyback SETI device was named SERENDIP and was used with the Hat Creek and Golstone antennas. It was recently upgraded to SERENDIP II, which has a 65,536-channel fast Fourier processor with a resolution of 2 Hz per channel. It will be used to search for narrowband peaks above a 6σ threshold over the entire 30-MHz IF band of the radiotelescope searching through increments of 100 kHz in 10 s or less. Data of unidentified peaks are recorded for further investigation. The system will operate unattended on a 24-h basis with practically any radiotelescope.

Many other parasitic searches have been carried out around the world. Thus while searching for impulsive radio events at 5 GHz with the 64-m Parkes radiotelescope in Australia, T. Cole and R. Ekers also checked a few G and K main-sequence stars for ETI signals of short duration. In a 4-day run they detected only one such signal in the direction of 82-Eridani which lasted only 1 ms. Efforts to re-acquire it were unsuccessful. During a routine search for pulsars with the large 100-m Bonn (Effelsberg) antenna, R. Wielebinski and J. Seiradakis of the Max Planck Institute for Radio Astronomy, looked for ETI pulsed signals at the hydrogen line with repetition periods between 0.3 and 1.5 s. And during a study of the galactic magnetic field with the 46-m Algonquin radiotelescope of Canada at 10.6 GHz (2.8 cm), Vallee²⁶ and Simard-Normandin of the Herzberg Institute also looked for highly (>70%) linearly polarized signals, which

Fig. 1 The regions of the sky that have been surveyed so far by the Ohio SETI Program³².

could be strongly suggestive of an artificial origin, near the centre of the Galaxy where a supercivilization could be operating an intergalactic relay station. Taking advantage of the fact that the 64-m antenna of NASA's Deep Space Station in Tidbinbilla, Australia, was stowed for several months for structural repairs, Gulkis, Kuiper, Olsen, Jauncey and Peters of the Jet Propulsion Laboratory used it for a SETI sky survey at 8 and 22 GHz with a 256-channel spectrum analyser. The elevation of the telescope was occasionally changed to scan a different band of the sky passing over it. Finally, the 1.5-m Mt Lemon optical telescope was used by F. Witteborn of NASA-Ames to further study 20 stars that in a routine infrared study had been found to be faint in the optical for their spectral type, but strong in the infrared. This made them potential candidates for Dyson Spheres, that is, the products of astroengineering activity by supercivilizations which could use all the planetary matter of their solar system to build a huge shell around their central star to tap a large fraction of its energy. Nothing was discovered that could not be explained by natural processes.

Turning to the Soviet Union, Slysh²⁷ and Kardashev²⁸ have also been looking in recent years for Dyson Spheres and other superstructures of astroengineering activity, searching primarily through the IRAS data for stellar sources with an unusual infrared signature. An all-sky search for microwave background fluctuations is under consideration by the Soviet workers to back up the IRAS data. Unfortunately during the past seven years there have been no radio searches in the Soviet Union, where there was considerable SETI, or CETI (Communication with ETI) as Soviet workers prefer to call it, activity in the 1960s and 1970s^{29,30} under the leadership of V. S. Troitskii and N. S. Kardashev. In the Proceedings of the Montreal meeting in 1979³¹ and at the SETI '81 meeting in Tallinn Estonia, Soviet workers had reported that they were preparing to start building in Gorki under the direction of Troitskii an array of ~100 1-m parabolic antennas (Project OBZOR) for SETI work at 21 cm. During my visit to Moscow in August 1984, I was told that this project had been abandoned, primarily because of the long illness of Troitskii—a pioneer and an international authority in this field. The emphasis in the Soviet Union is now geared towards the detection of astroengineering structures by supercivilizations, but I feel that under the leadership of Kardashev and Slysh, they will regain their high-ranking position in the radio searches, especially with the use for SETI of the new 65-mm Samarkand millimetre radiotelescope now approaching completion.

Dedicated searches

Dedicated searches are performed by radio observatories that have become SETI dedicated facilities and conduct searches on a continuous basis. There are two such projects now in operation,

which account for ~80% of the observing hours accumulated thus far. The oldest of the two is the Ohio SETI Program, having been in operation since 1973 under the direction of J. Kraus and R. Dixon³². It uses the meridian-transit radiotelescope of the Ohio State University which has a collecting area of 2,200 m², equivalent to a parabolic dish 53 m (175 ft) in diameter, and a beam pattern at 21 cm of 8 arc min in RA and 40 arc min in dec. The search is conducted at the hydrogen line, Doppler shifted in the rest frame of the galactic centre, with the help of a 50-channel filter bank with a resolution of 10 kHz per channel. During the first 3 yr (1973–76), however, the system was less sophisticated and operated with only eight channels. Figure 1 shows the portions of the accessible sky (–36 to +63 in declination) that have been covered thus far by the old and the new system. The sky band 40–43 dec was chosen because it includes the Andromeda Galaxy (M31), our large neighbouring galaxy.

The 'WOW' signal of the Ohio SETI Program (Fig. 1) was recorded in 1977 at –27 dec. It earned its name from the word the telescope operator penned next to this peak on the computer printout of the telescope, and in spite of repeated efforts by the Ohio group and others it has never been re-acquired. The data obtained are archived and analysed for statistical effects with respect to celestial coordinates. Several improvements are being planned for the future, including expanding the frequency range to cover the entire 'water hole' (1,400–1,750 MHz) which is bracketed by the hydrogen and the OH lines, that together form water. The Ohio SETI Program has been sustained with modest support from NASA, the tireless efforts of Kraus and Dixon, and the unselfish dedication of many enthusiastic volunteers.

Horowitz³³ of Harvard University and his collaborators have been operating since March 1983 the other dedicated facility at the Oak Ridge Harvard-Smithsonian Observatory near Boston. It is called Project SENTINEL and is supported by the Planetary Society, a private organization headed by C. Sagan and B. Murray. It is an outgrowth of project Suitcase SETI mentioned earlier, and uses the same two 65,536-channel spectrum analysers, with a resolution of 0.03 Hz per channel, with the 84-ft antenna of the Oak Ridge Observatory. With the telescope set at a particular declination, the search sweeps a 0.5° band around the sky, covering the entire available sky (about 80% of total) in ~1 yr. During their 2 yr of operation (1983–85) they have covered all of the accessible sky, first at the hydrogen line at 1,420.40575 MHz and then at one of the four OH lines at 1,667.3590 MHz. A potential source stays in the antenna beam for about 2.5 min. The system searches automatically for large peaks in any of its channels and archives anything suspicious. Because of the expected swept-Doppler signature produced by the Earth's rotation, the system is very good in rejecting radio interference, though they too had two false alarms of almost 50σ when they got the Sun into their beam.

The problem with this search is its very narrow (2 kHz) total bandwidth around the hydrogen line. This necessitates a continuous correction for all the Doppler shifts due to the motions of the Earth relative to the direction of the antenna, and assumes that the transmitting civilization will also correct for all Doppler shifts, including the relative motion of our two stars (the radial component of the peculiar motion) which can be of the order of 100 kHz, that is 50 times larger than the 2-kHz total bandwidth of the system. It also requires that they beam their signals specifically to our Solar System. To overcome these restrictions, Horowitz and his colleagues³⁴ have built a brand new MCSA with 8.4×10^6 channels and a frequency resolution of 0.05 Hz per channel, which is giving them a total bandwidth of 420 kHz, enough to account for practically all of the Doppler effects. In the 2.5 min that a source stays in their antenna beam the system will make six and possibly eight measurements checking the left-hand and the right-hand circular polarization at three or four distinct frequencies of the same line resulting from Doppler effects in three or four different rest frames (the local standard of rest of our Solar System and possibly their heliocentric frame, the reference frame of the galactic centre, and the cosmic black-body rest frame in which the 3 K background radiation is

Fig. 2 The microwave window of interstellar space³⁸.

isotropic). This new system, which has been named Project META, went into operation on September 29, 1985.

Technological progress and NASA's Program

The search for ETI radio signals is a multidimensional problem which because of its complexity is often called the 'cosmic haystack'. The dimensions of the search space include: location of sources; transmitting frequency; signal strength; bandwidth; polarization; signal modulation; and on-off periods. Initially investigators in the United States had hoped that ETI would be transmitting at the hydrogen line to make contact easy. But extensive, although not exhaustive, searches by many investigators at hydrogen and a few other magic frequencies have not produced any positive results, which indicates that the search is not going to be an easy task. With the improvement in our technology, NASA is now preparing to embark on the next generation of radio searches, that is a systematic search over a wide frequency range (rather than the old magic frequencies) in the microwave window (1–10 GHz) of the Earth. This is the free-space microwave window seen on Fig. 2, cut off for ground observations around 10 GHz by the water vapour in the Earth's atmosphere. This frequency range is relatively free of natural radio noise, and is therefore best suited for interstellar communications. Embedded deep in the microwave window is the 'water hole' (1.4–1.7 GHz), probably the most attractive frequency range for interstellar radio communications. A point of great concern, however, is the rapidly growing use of this frequency range for other purposes, which are bound to interfere with future radio searches.

It is generally believed that radio signals will be narrowband to reduce peak power. To have a good signal-to-noise ratio we need receivers with very narrow bandwidths, and since we need to explore a wide frequency range we need a large number of narrowband channels. This function is fulfilled by a MCSA³⁵, an electronic high-resolution radio spectrometer, which in the past 25 yr has evolved from a few channels to 65,000 channels and we are soon to have MCSAs with 8×10^6 channels and possibly more. We have already mentioned the ultra-narrowband MCSA constructed by Horowitz for his Project META. NASA is also planning an 8.25×10^6 -channel MCSA, but with a much wider total bandwidth, which is now being developed by a group at Stanford University headed by Peterson³⁶ and Linscott. It will consist of two cascaded banks of digital filters followed by multiplexed microprocessors executing digital Fourier transforms. The complete MCSA will have 112 units, each with 73,728 channels for a total of 8,257,536 channels. The highest frequency resolution will be 1 Hz per channel, giving a total bandwidth of about 8 MHz. It will also be able to analyse simultaneously the incoming 8-MHz frequency band into channels of 32, 1,024 and 73,728 Hz. In all cases, it will examine both the left-hand and the right-hand circular polarizations.

The MCSA performs a complex Fourier transform that yields the real and imaginary amplitude of the signal, which are then

Fig. 3 The two 'volumes' of the SETI Search Space, that will be searched by the Sky survey and the Targeted search, the two complementary components of the NASA SETI Program⁴⁰.

squared and added to give the actual power for each bin (channel). If it exceeds a predetermined threshold, chosen by the desired signal-to-noise ratio, the signal is flagged for further tests. Sophisticated signal detection algorithms^{35–37} are now being developed by NASA. Considerable effort is being made to achieve online processing of the data, which is not an easy task given the huge volume of incoming data with an 8×10^6 -channel MCSA. Emphasis is also placed on the ability to detect pulsed signals and signals with a Doppler frequency drift³⁷. The 8×10^6 channel MCSA could be ready by 1988, but more realistically the whole system, including all the signal processing instrumentation, will probably become operational in the early 1990s. A prototype unit with 73,728 channels, together with several of the new signal recognition algorithms, is now undergoing tests at the Goldstone antenna. In a recent test, they were able to pick up the very weak signal (1 W) beamed by Pioneer 10 towards the Earth from a distance of ~35 AU ($\sim 5,250 \times 10^6$ km). They were also able to see clearly the frequency drifts imposed on this monochromatic signal by the rotation of the Earth and the relative motion of the Earth and the spacecraft.

The NASA SETI Program³⁸, which has been in the study and development stage for the past 15 yr, is now headed by B. Oliver, one of the pioneers of SETI⁷, and includes about 15 well-known scientists at the three California institutions (NASA-Ames, Jet Propulsion Laboratory, and Stanford University) that share responsibility for this programme. The NASA SETI Program will be a bimodal search consisting of two components: the Targeted search³⁹, which will emphasize sensitivity to weak signals by concentrating only on a number of discrete sources, and the Sky survey^{40–42}, which will emphasize sky coverage by scanning the entire sky. Figure 3 shows the relative volumes of the search space that will be investigated by these two complementary searches.

The Targeted search will focus on 800–1,000 specific targets, including the 773 F, G and K Sun-like stars up to a distance of 25 pc (81.5 light yr) included in the Royal Greenwich Observatory Catalogue, and a variety of other targets including stars with peculiar spectra and galaxies. It will have a peak spectral resolution of 1 Hz and will concentrate in the frequency range surrounding the water hole. The sensitivity (Φ) of radio observations, usually given in W m^{-2} , is related to the demanded signal-to-noise ratio (a), the system temperature (T), the collecting area of the antenna (A) which is proportional to the square of the diameter (D) of the antenna, the resolution bandwidth (b), and the integration time (τ), by the expression:

$$\Phi = a \frac{kT}{A} \left(\frac{b}{\tau} \right)^{1/2} \quad (1)$$

Since for given Φ , T and b , τ is proportional to D^4 , to achieve the highest possible sensitivity in a reasonable time, the targeted

search will use the largest possible antennas including the 305-m Arecibo, the 53-m (equivalent) Ohio State, the 64-m Goldstone (California) and Tidbinbilla (Australia) antennas of NASA's Deep Space Network, the 91-m NRAO, and possibly the 100-m Bonn (Germany) antenna. It is interesting to note that when the 1,000-ft Arecibo antenna with a system temperature of 35 K is compared with Drake's 85-ft NRAO antenna with a 350 K system temperature, Arecibo would be able to do the 200 h of Project OZMA in just a fraction of a second.

An approximate time calculation for the Targeted search yields 1,000 targets \times 1,000 s per target per 8-MHz frequency band \times 100 frequency bands to cover the range 1.2–2.0 GHz around the water hole $= 10^8$ s $=$ 3.3 yr, which, including losses of time for moving the antenna from target to target, antenna maintenance, transportation of the MCSA from station to station, and so on, amounts to \sim 5 yr of telescope availability. The Sky survey will use several of the smaller, 34-m radio-telescopes in NASA's Deep Space Network. It will have a lower spectral resolution of 32 Hz per channel, but will cover a wider frequency range (1–10 GHz). It will survey the entire sky (4π sr) with a half-power beamwidth (HPBW) of $\sim \lambda/D$ and therefore will, in essence, examine $4\pi/(\lambda/D)^2 \sim 10^6$ locations. Spending from 0.3 to 3 s per location (to scan through a HPBW) and per frequency band of about 250 MHz, and needing \sim 36 such bands to cover the 1–10 GHz range, yields again a total of $\sim 10^8$ s, that is also \sim 5 yr of telescope availability. Thus the entire NASA SETI Program (Targeted search and Sky survey) will require \sim 10 yr telescope availability. Using 5–10 different radiotelescopes at \sim 10–20% of their time, and assuming the availability of several MCSA units, the whole programme will take optimistically \sim 5 yr, but more realistically probably close to 10 yr. Hence assuming a starting date around 1990, we can expect it to be completed around the year 2000, having enhanced immensely the volume of the search space that we will have explored. It is also possible that a high spectral resolution search, such as this, over the entire sky and over a wide frequency range, might produce also some unexpected astronomical discoveries.

Rationale behind the search strategy

Sparked off by a critical paper by Hart⁴³ in 1975, there were many heated debates⁴⁴ and counter-arguments⁴⁵ in the late 1970s and early 1980s on the most advisable search strategy and even on the advisability of undertaking any searches at all. The key points to these debates were: (1) the possibility of interstellar travel and of galactic colonization, and (2) the lack of any scientifically verifiable evidence of visits to Earth by extraterrestrials, which is often referred to as the 'Fermi Paradox' or the 'Great Silence'⁴⁶. After many debates, we began to realize that none of us can claim to know how civilizations far more advanced than ours are likely to behave and act. The conclusion, therefore, which was stated by several participants^{46–50} at the recent IAU Symposium¹³ can be summarized as follows: debates, useful as they might be to sharpen our understanding of the issues, will never answer our questions. The answers can come only through scientific searches, which must be pursued vigorously. The search strategy, however, ought to be broad and flexible enough to allow, besides the mainstream searches such as the NASA SETI Program, the parallel experimental testing of different other theoretical possibilities. With such a broader search strategy we are likely to keep many more good people active in this young field, and at the same time increase our chances of success by not neglecting any of the possible alternatives.

From a comparison of Project OZMA and Arecibo with an MCSA, it is clear that we have made colossal technological progress in less than three decades. A question often asked is why we do not postpone our searches until our technology becomes more effective. I believe the answer has two parts. The first is that we do not know in advance the level of technology that would be sufficient. It would have been a grave mistake to have asked Wilbur and Orville Wright to wait for the discovery of the jet engine before trying to fly. They succeeded with far

less, and on 17 December 1903 they opened the doors of the new field of aviation. I am sure that even if Drake could have known that 25 yr later Horowitz would have had an 8×10^6 MCSA for a search around the hydrogen line, he still would have gone ahead with his Project OZMA, and rightfully so. The second reason is that technology is like a ladder that we must climb one rung at a time, starting from the lowest ones. But as we start climbing, the horizons broaden and many new technological developments materialize, such as the jet engine in aviation and the 8×10^6 MCSA in SETI, with benefits also for many other fields.

After millennia of thinking and philosophizing about the 'plurality of worlds', we have finally entered the experimental era. We have already used space probes to search for primitive life in our Solar System, and we are now searching with radio, optical and infrared telescopes for other advanced civilizations in the Galaxy. It is a special privilege to live in the era that tries to answer experimentally profound old questions about the prevalence of life, and especially of life with intelligence, in the Universe. With the NASA SETI Program as the central force, and the many other parallel special searches now in progress or planned for the future, we can expect that in the next 10–20 years we will know much more about the presence of other advanced civilizations in our Galaxy. If we were to find them, this would be the greatest discovery of all time. But even if after concerted efforts we were to conclude that we must be one of very few if not the only advanced civilization in the Galaxy, this too would be an important discovery, because knowing how rare our civilization is among the hundreds of billions of stars in our Galaxy would hopefully make us realize how cosmically important it is to preserve it.

I thank the many contributors to the *Proceedings of the IAU Symposium 112*¹³ whose works helped me in the preparation of this review. I also thank my colleagues, especially J. Billingham, D. DeVincenzi, R. Dixon, F. Drake, S. Gulkis, H. Hirabayashi, P. Horowitz, J. Jugaku, N. Kardashev, M. Klein, B. Oliver, C. Sagan, C. Seeger, V. Slysh, W. Sullivan, J. Tarter and V. Troitskii, for useful discussions and comments on the first draft of this article. This work was supported by NASA grant NAGW-597.

Intensive measurements of turbulence and shear in the equatorial undercurrent

M. C. Gregg*, H. Peters*, J. C. Wesson*, N. S. Oakey† & T. J. Shay*

* Applied Physics Laboratory and School of Oceanography, College of Ocean and Fishery Sciences, University of Washington, Seattle, Washington 98195, USA

† Bedford Institute of Oceanography, Dartmouth, Nova Scotia, Canada

Average profiles of turbulent dissipation rates provide tests of parameterizations used in numerical models. A strong diurnal mixing cycle is found in the well-stratified high-shear zone above the velocity maximum, and thermohaline intrusions are shown to be important mixing agents below the velocity maximum.

INTENSE and persistent mixing occurs in the equatorial undercurrents of the Atlantic and the Pacific oceans. Determining and parameterizing the average turbulent fluxes is necessary because these fluxes may provide the primary dynamical balance to the pressure gradient driving the undercurrent. Turbulent transport in the undercurrent is particularly important in the central Pacific, where it is a major factor controlling the tongue of cold water extending westward from South America¹. Temperature changes of the cold tongue affect the air-sea interactions that lead to anomalous weather conditions over North America. Therefore, improving the measurement and parameterization of the vertical turbulent fluxes in the undercurrent is a major goal of the Tropic Heat Program established to study the cold tongue¹. The undercurrent also provides an excellent natural laboratory for studying stratified turbulence.

Although the amount of previous turbulence data from the undercurrent is small, microstructure profiles taken at various locations and times, with different instruments, show similar patterns and intensities^{2–5}. Earlier measurements with towed bodies report levels at the core of the undercurrent that are several decades higher than those observed with profilers^{6,7}, leading some to conclude that the towed data are badly contaminated by vibration and sensor difficulties^{2,5}. Others maintain that large intermittence at the velocity maximum produces the disparity⁸.

Between 25 and 30 November 1984, during the Tropic Heat field measurements, continuous profiling of turbulence was done in the upper 150 m at 0° N, 139°50' W with the advanced microstructure profiler (AMP)⁹. In 4.5 days, 385 drops were obtained, providing enough data to form accurate ensemble average profiles and to examine short-term fluctuations. Also, eight shear measurements were obtained with the expendable current profiler (XCP)¹⁰.

Background conditions

The average stratification and shear are typical of conditions near 0° N, 140° W. The mean stability frequency, \bar{N} , is low near the surface but increases rapidly, reaching a maximum of 0.02 s^{-1} near a pressure (p) of 1.0 MPa (corresponding to a depth of 100 m). Close to the surface the stratification is controlled by temperature, but salinity is important below 0.65 MPa. Because the XCP measures relative velocities, the average speed between 5.0 and 5.5 MPa is set to zero, in general agreement with mooring observations. Useful signals from the XCP begin at 0.3 MPa;

the transport at shallower depths is to the west, as observed from the ship drift. The zonal flow below 0.3 MPa is eastward (zonal velocity $\bar{U} > 0$ in Fig. 1), reaching 1.6 m s^{-1} near 1.05 MPa, which is close to the depth of the salinity maximum. Owing to the proximity of the magnetic equator the north component of the XCP signal is not useful. Nevertheless, because of the dominance of the eastward flow, good estimates of shear are obtained from $\partial \bar{U} / \partial z$ (where z is the depth). Values are calculated from the slopes of linear fits to the raw velocity components. The interval of each fit is 0.2 MPa, and a fit is done every 0.05 MPa. Shear decreases with depth and has a local minimum at the velocity maximum. Because this occurs close to \bar{N}_{max} , the Richardson number, $Ri \equiv \bar{N}^2 (\partial \bar{U} / \partial z)^{-2}$, has a sharp maximum. Above 0.5 MPa, $Ri < 0.25$; between 0.5 and 0.9 MPa, it is about 0.35 (Fig. 2). Based on fluctuations in the eight shear profiles used to form the average, we estimate typical confidence limits to be (0.0–0.15) for $Ri = 0.07$ and (0.2–0.5) for $Ri = 0.3$. Vertical smearing, due to displacements by internal waves and the internal tide, makes the velocity maximum appear thicker and reduces the maximum value. $Ri < Ri_{\text{cr}} \equiv 0.25$ is a necessary but not sufficient condition for instability of laminar flows¹¹.

Average mixing rates above velocity maximum

Centimetre-scale gradients of horizontal velocity and temperature measured with AMP are used to compute the variances of the gradients over successive 0.005 MPa (0.5-m) sections. Scaling yields $\epsilon = 7.5 \nu \langle (\partial U' / \partial z)^2 \rangle$ and $\chi = 6 \kappa_T \langle (\partial T' / \partial z)^2 \rangle$. ϵ is the rate of viscous dissipation of turbulent kinetic energy, and χ is the rate of diffusive smoothing of turbulent temperature fluctuations. (ν is the kinematic viscosity and κ_T is the thermal diffusivity.) In both cases, isotropy of the microscale gradients is assumed.

Because of the large number of records taken in a short time, average profiles of ϵ and χ can be formed using all data in each 0.005 MPa pressure bin (Fig. 3). Comparison with laboratory results provides a measure of the relative intensity of $\bar{\epsilon}$. Studies of decaying grid turbulence in unsheared flows¹² show that when $\epsilon > \epsilon_{\text{tr}} = 24.5 \nu N^2$, the turbulence will be sufficiently intense to produce a negative buoyancy flux, that is, $J_b \equiv -g \rho^{-1} w' \rho' < 0$ where g is the gravitational acceleration, ρ' is the density and w' is the vertical velocity. A negative buoyancy flux corresponds to an upward mass flux, which increases the mean potential energy. Preliminary results from sheared flows¹³ show that the

Fig. 1 Average profiles of the stratification and velocity fields; θ is potential temperature, s is salinity (in concentration units), σ_θ is potential density, p is pressure, and U is the zonal velocity (positive east). These plots are formed from averages of 385 AMP profiles and eight XCP profiles. Owing to vertical displacement by internal waves and the internal tide, averaging smooths small-scale structures in these profiles. Both the depth of the velocity maximum, 1.1 MPa (110 m), and its association with the salinity maximum are typical near 0° N, 140° W. The stability frequency, N , is computed from the average temperature and salinity profiles and peaks slightly above the velocity maximum, producing a sharp maximum in the Richardson number, Ri .

Fig. 2 The average Richardson number, Ri , and dissipation rates. Where $Ri < 1$, $\bar{\epsilon}(p) > \epsilon_{tr}$, the threshold for active turbulence. $\bar{\chi}(p)$ follows a similar pattern, modified by the local temperature gradient. The turbulent eddy coefficients for heat, K_h , and momentum, K_m (dashed line), are approximately equal between 0.3 and 0.9 MPa. The corresponding turbulent fluxes, J_q and J_m (dashed line), follow similar patterns, having large values near 0.3 MPa and decaying to about 0 at the Ri maximum.

same criterion holds when $Ri > 0.25$; when $Ri < 0.25$ the turbulence does not decay.

In the undercurrent, $\bar{\epsilon}$ decreases with depth (Fig. 2). Above 0.4 MPa, $Ri < 0.1$ and $\bar{\epsilon}$ exceeds ϵ_{tr} by at least two decades. This ratio decreases to about 20 between 0.6 and 0.9 MPa, where $1/4 < Ri < 1/2$. It then drops rapidly and crosses 1 where $Ri = 1$. Thus, in most of the high-shear zone above the velocity maximum the average dissipation rates indicate strongly active turbulence, producing a net buoyancy flux.

In steady, homogeneous turbulence, the balance equation for turbulent kinetic energy reduces to local production and dissipation. If the mean shear is strong, the turbulent production can be expressed as a vertical eddy coefficient for momentum, K_m

$$K_m = \frac{\epsilon}{(1 - R_f)(\partial \bar{U}/\partial z)^2} \quad \text{m}^2 \text{s}^{-1} \quad (1)$$

where R_f is the flux Richardson number. Because $R_f \leq 0.15$ this term is a small correction and is ignored. The corresponding vertical momentum flux is

$$J_m = -\rho K_m \frac{\partial \bar{U}}{\partial z} \quad \text{kg m}^{-1} \text{s}^{-2} \quad (2)$$

In studies of the planetary boundary layer of the atmosphere, this procedure is known as the dissipation method and has been verified by comparison with direct flux measurements. If the temperature fluctuations are produced by turbulent overturns against the mean gradient, rather than by lateral advection, a similar balance applies with the T^2 -balance equation, yielding

the turbulent transport coefficient for heat, K_h , and the vertical turbulent heat flux, J_q :

$$K_h = \frac{\chi}{2(\partial \bar{T}/\partial z)^2} \quad \text{m}^2 \text{s}^{-1} \quad (3)$$

$$J_q = -\rho C_p K_h \frac{\partial \bar{T}}{\partial z} \quad \text{W kg}^{-1} \quad (4)$$

This approach, known as the Osborn-Cox method¹⁴, is widely used to obtain turbulent heat fluxes in the thermocline.

Equations (1) and (3) have been used with previous measurements in the undercurrent to develop parameterizations for numerical models^{15,16}. Their use has not been verified in the ocean by comparison with direct flux measurements, but conditions between 0.3 and 0.9 MPa are more appropriate to the dissipation method than any other known section in the ocean, and the present data offer much greater statistical confidence than previously available. Above 0.9 MPa, K_m and K_h are nearly equal, that is, the turbulent Prandtl number is close to one, and they decrease rapidly with depth. At 0.3 MPa, $K_m \approx K_h \approx 2 \times 10^{-3} \text{ m}^2 \text{s}^{-1}$, and at 0.9 MPa, $K_m \approx K_h \approx 6 \times 10^{-5} \text{ m}^2 \text{s}^{-1}$, a decrease by a factor of 25. Over the same interval, J_q drops from 140 to 20 W m^{-2} . (J_q decreases relatively less than K_h because $\partial \bar{T}/\partial z$ also decreases.)

Average mixing rates at velocity maximum

At the velocity maximum, the dissipation rate has a minimum, $\bar{\epsilon} = 2 \times 10^{-9} \text{ W kg}^{-1}$, which is about a quarter of ϵ_{tr} . Because $\epsilon < \epsilon_{tr}$, dissipation-scale fluctuations are less likely to be isotropic

Fig. 3 Five-hour running means of the surface heat flux, of ϵ , and of N , showing a diurnal cycle in ϵ penetrating deep into the thermocline. The surface heat flux (solid line in the top panels) is dominated by the short-wave radiation (dashed), and by the latent heat flux (dotted). The time series for ϵ and N are averages over successive 0.1-MPa intervals; for example, the first set, labelled 0.15, are averages between 0.1 and 0.2 MPa. The curves for pressures >0.15 MPa are successively offset by one decade in ϵ and N , respectively. The diurnal cycle in ϵ remains distinct to 0.65 MPa and has some deeper signatures, unlike the diurnal N cycle, which is weak at 0.25 MPa and absent deeper. The daily minimum in ϵ has a progressive phase lag with depth, as shown by the slanting lines.

than at shallower depths. The maximum effect of anisotropy is to reduce $\bar{\chi}$ by a factor of 3. The effect on $\bar{\epsilon}$ is more difficult to estimate, but should be at least as large. Thus, if the microstructure at the core is anisotropic in the dissipation range, $\bar{\epsilon}$ and $\bar{\chi}$ will be even smaller compared with the levels in the high-shear zone shown in Fig. 2.

To remove the effects of displacements by internal waves and the internal tide, a preliminary statistical analysis was done on all 0.5-m ϵ values between potential density, $\sigma_\theta = 24.6$ and 25.5, which spans the velocity maximum. This yields $\bar{\epsilon} = 4.7 \times 10^{-9} \text{ W kg}^{-1}$ which is only a factor of three higher than an average found in a quiet region of the California Current¹⁷ and is almost three decades lower than the values reported from towed measurements^{6,7}. A probability distribution does not reveal any greater degree of intermittence than in other locations. For example, using the standard deviation of $\ln \epsilon$ as the measure of intermittence⁸, $\sigma_{\ln \epsilon} = 2.4$ compared with $\sigma_{\ln \epsilon} = 2.3$ from the California Current¹⁷. Using this in the maximum-likelihood estimate suggested for intermittent turbulence⁸ yields a value smaller than the arithmetic mean, that is, $\epsilon_{\text{mle}} = 4.2 \times 10^{-9} \text{ W kg}^{-1}$, because the distribution is skewed to low values and has a median of $2.2 \times 10^{-10} \text{ W kg}^{-1}$. Therefore, these data do not reveal unusual intermittence at the velocity maximum, but indicate that the conditions are similar to those in the main thermocline at less energetic locations.

Because the shear passes through zero, conditions are not appropriate for the dissipation method, and K_m is not calculated. The estimate of K_h is not affected, however, because the temperature gradient remains large, and $K_h \approx 1 \times 10^{-6} \text{ m}^2 \text{ s}^{-1}$. This is about 10 times κ_T , the molecular diffusion coefficient, and provides additional evidence that mixing levels at the velocity maximum are weak.

The diurnal cycle

Daily fluctuations, by factors of 10 to 100 in ϵ and χ , exist both in the diurnal mixed layer and in the well-stratified profile below (Fig. 3). The cycle extends to between 0.75 and 0.95 MPa, even though day-to-day variability not related to changes in the surface heat flux is also apparent.

Between 0.1 and 0.3 MPa, both the mixing and the stratification change in phase with the surface heat flux, which is dominated by the short-wave radiation and the latent heat flux. (The sensible heat flux is negligible by comparison, varying between -12 and $+20 \text{ W m}^{-2}$.) At night, the net flux is $\approx 200 \text{ W m}^{-2}$ out of the sea, corresponding to a surface buoyancy flux of $J_b^0 = 3.2 \times 10^{-7} \text{ W kg}^{-1}$, producing a well-mixed layer extending to between 0.2 and 0.3 MPa.

Fig. 4 Comparison of the averages of all profiles within 1 h of local noon and of local midnight. The mixed layer extends to 0.2 MPa at midnight, but is fully restratified by noon. Above 0.1 MPa the mixing rates are dominated by wind forcing, but between 0.15 and 0.65 MPa the diurnal cycle is evident. At noon, the turbulence is most heavily suppressed near 0.25 MPa. The observed vertical displacements, l_v , are independent measures of changes in ϵ and agree well with the Ozmidov scale, L_o , computed from the dissipation rates and stratification. At 0.25 MPa, the turbulent heat flux, J_q , drops from 240 W m^{-2} at midnight to 30 W m^{-2} at noon.

Observations in another convecting mixed layer show $\bar{\epsilon} \approx J_b^0$ within the mixed layer and below the zone affected by the wind¹⁸. In this case, which was in a region with a moderate mean shear, the mixed layer terminated in a sharp density step and the dissipation rates below the entrainment zone decreased several decades. A profile of $\bar{\epsilon}$ for midnight shows a minimum of $4 \times 10^{-7} \text{ W kg}^{-1}$ below the surface zone, followed by an increase to $1 \times 10^{-6} \text{ W kg}^{-1}$ at 0.3 MPa (Fig. 4). Thus, the turbulence produced by convection may account for a substantial fraction of the observed $\bar{\epsilon}$ above 0.3 MPa, but production by the mean shear or wind mixing is also present. The shape of the average midnight temperature profile is similar to individual realizations and shows a smooth transition to the stratified regime. This is very different from the abrupt termination of convecting mixed layers where the deeper water has low dissipation rates¹⁸. We believe this is due to the intense turbulence in the stratified section as well as in the mixed layer. Above 0.3 MPa, $\bar{\epsilon}$ is a minimum at noon, when the profile has maximum stratification. Below 0.3 MPa the diurnal ϵ cycle remains large and is 1.5 decades at 0.65 MPa (Fig. 3), even though there is day-to-day

Fig. 5 An AMP drop showing multiple salinity maxima and minima below 1 MPa, indicating the importance of lateral advection. The deepest of the three intrusions occurs where $Ri < 1$ and has strong mixing between 1.25 and 1.4 MPa, where the profile is diffusively unstable to salt fingering. The pattern of activity is similar to that found in highly sheared intrusions in a warm-core Gulf Stream ring¹⁶. This profile was taken at 20.53 GMT, or 10.53 LT, and has relatively weak dissipation rates between 0.3 and 0.9 MPa and on the intrusions where $Ri > 1$.

variability. The cycle is not symmetric, but has maxima lasting longer than the minima. Examination of more detailed plots shows that decreases in ϵ begin nearly simultaneously with depth. Nevertheless, the minimum has a phase lag that increases downward (Fig. 3). At 0.65 MPa, the lag is 3–6 h after local noon.

Between 0.3 and 0.9 MPa the diurnal cycles in ϵ and χ produce large changes in the overturning scales of the turbulence and in J_q (Fig. 4). Two measures of overturning are used: the Ozmidov scale, $L_o \equiv \epsilon^{1/2} N^{-3/2}$, and l_r , the root-mean-square displacement computed by comparing the observed σ_θ profiles with resorted monotonic versions of the same data^{19,20}. The two scales show good agreement. Below 0.3 MPa, the overturning scales at noon are only a few tens of centimetres, but, during the night, they grow to a few metres. Correspondingly, J_q increases from about 30 W m^{-2} at noon to about 240 W m^{-2} at midnight. At night these estimates are unreliable above 0.25 MPa owing to the weak stratification in the mixed layer.

Thermohaline intrusions from 1.0 to 1.5 MPa

Between 1.0 and 1.5 MPa, thermohaline intrusions strongly affect ϵ and χ . Although temperature usually decreases monotonically over scales greater than 1 m, salinity has a sequence of maxima and minima (Fig. 5). These can only be of advective origin, and are probably associated with the salinity front near the Equator²¹. Changes between successive profiles indicate that the intrusions have horizontal scales less than a few kilometres. Very high dissipation rates occur beneath the salinity maximum of some intrusions. For example, comparing Fig. 5 with the average profiles in Fig. 2 shows that between 1.3 and 1.4 MPa ϵ is as high as $\bar{\epsilon}$ at 0.3 MPa, and χ is higher than $\bar{\chi}$. A similar pattern, found on thermohaline intrusions in a warm-core ring, was attributed to a combination of salt fingering and the shear of near-inertial motions²². Because strong lateral processes, and possibly salt fingering, are involved, neither the dissipation method nor the Osborn-Cox model are applicable to the mean profiles in this pressure range.

Discussion

Based on profiles of $\bar{\epsilon}$ and $\bar{\chi}$, five mixing zones are found in the upper 1.5 MPa below the near-surface zone: (1) the diurnal mixed layer, 0.1–0.3 MPa, has high dissipation rates, which are modulated by almost a factor of 100 and are in phase with the surface heat flux; (2) the upper high-shear zone, 0.3–0.9 MPa, has dissipation rates and turbulent fluxes that are high just below the mixed layer but decrease with depth, as Ri increases. At a given depth, the dissipation rates vary by factors of 10 to 100

in a diurnal cycle; (3) the velocity maximum, 0.9 to 1.25 MPa, has low dissipation rates, similar to those in mid-gyre; and (4) the lower high-shear zone, 1.25 to 1.5 MPa, has high dissipation rates when thermohaline intrusions occur.

The patterns and magnitudes of these observations are consistent with previous profiles in the undercurrent and are inconsistent with the towed observations. Discovery of the diurnal cycle in the stratified region below the surface mixed layer and of the role of thermohaline intrusions in the dissipation below the core is new.

The daily ϵ cycle is nearly as strong between 0.3 and 0.65 MPa as in the diurnal mixed layer. This is a surprise in view of the restricted depth range of the diurnal cycle in stratification. N variations are readily apparent (Fig. 3), but they have no diurnal signature similar to that in ϵ and χ . To our knowledge no previous observations have been reported, from any location, of a diurnal cycle below the mixed layer and its entrainment zone.

We have considered several possible causes of the deep diurnal mixing cycle: the absorption of solar radiation, a diurnal cycle in the large-scale shear, and daily modulation of high-frequency internal waves.

Suppression of the turbulence by a buoyancy flux resulting from the absorption of solar radiation seemed a likely mechanism when we noticed the diurnal cycle at sea and has since been suggested to us by several others (M. Lewis and J. D. Woods, personal communications). We do not, however, understand how this can happen without also producing a daily cycle in N , which is not apparent in Fig. 3 or in other more detailed plots.

No diurnal shear cycle has been reported from the Equator; but, in response to discovery of the diurnal mixing cycle, current meter records from moorings at 0°N , 140°W in May and November 1983 have been examined (D. Halpern, personal communication). Between 0.1 and 0.25 MPa, shear has a strong daily fluctuation, $\sim 0.01 \text{ s}^{-1}$, but this decreases rapidly with depth and is negligible below the diurnal mixed layer, especially compared with the semi-diurnal tidal signal.

Internal wave energy on the equator is higher than found in mid-gyre²³, and laboratory studies show that mixed layer turbulence can generate internal waves in the thermocline²⁴. Therefore, internal waves, generated when turbulence is strong in the mixed layer, may propagate downward and break in the stratified high-shear zone, producing much of the observed mixing. When the surface layer restratifies during the day the source of internal waves will be suppressed, leading to a minimum in mixing below the mixed layer which may have a phase lag as the effect propagates downward.

Fig. 6 Comparison of K_m and K_h obtained using the dissipation method (*) with parameterizations used in two numerical models of the undercurrent. Dashed line, from ref. 15; solid line, from ref. 16. The model K_m and K_h are functions of the observed $\bar{N}(p)$ and/or $Ri(p)$. The parameterizations are closer where Ri is low, above 0.7 MPa, than where Ri is high.

The data available to us are inadequate to determine whether one of these mechanisms is the cause, because small changes in either N or shear could be responsible. Mixing in this zone resembles a sharply tuned harmonic oscillator, which can have large output changes for small forcing perturbations. Plotting the $\bar{\epsilon}$ profile as a function of Ri shows a large increase when Ri drops below 0.25. Consequently, a 20% increase in shear or a similar decrease in N can change the average Richardson number from 0.35 to 0.25. Figure 3 shows much larger changes occurring in N , but with no apparent daily frequency. The eight XCP profiles show that the shear also changes by more than 20%. Because a wide band of frequencies seem to contribute to changes in both N and shear, longer time series of both are needed to define a diurnal signature. Data taken by other Tropic Heat investigators may be able to resolve this, but we know of no measurements that can examine the role of high-frequency internal waves and recommend that such measurements be included in future experiments.

In addition to taking the time series on the Equator we made measurements at 0.5° intervals off the Equator and found that the diurnal cycle extended to at least 1.0 MPa just outside of the undercurrent, compared with 0.3 MPa, in the centre of the undercurrent. It is possible that internal waves radiated from these deeper layers are also involved and that the problem is three-dimensional rather than just one-dimensional.

Two recent numerical models of the undercurrent are based on previous microstructure observations. One parameterizes the eddy coefficients in terms of N , largely for mathematical convenience¹⁵

$$K_m = K_h = AN^{-2} \quad (5)$$

with A chosen to produce $K_m = 5.5 \times 10^{-5} \text{ m}^2 \text{ s}^{-1}$ at N_{max} . Another¹⁶ bases the parameterization on Ri

$$K_m = 1 \times 10^{-4} + \frac{5.5 \times 10^{-3}}{(1 + 5 Ri)^2} \quad (6)$$

and

$$K_h = 1 \times 10^{-5} + \frac{K_m}{1 + 5 Ri} \quad (7)$$

Comparison with our estimates, using equations (1) and (3), shows that equation (6) is consistently high, except between 0.5 and 0.7 MPa (Fig. 6). Equation (7) agrees remarkably well with observations above 0.7 MPa, but is an overestimate at greater depths. Equation (5) agrees relatively well with observations for K_m , but is low by factors of 2–5 between 0.4 and 0.7 MPa. For K_h , equation (5) has much less vertical change than the observations, and crosses from an under to an over estimate near 0.7 MPa. At 1.1 MPa, it is almost a factor of 100 too high.

Both parameterizations are in rough agreement with K_m and K_h computed from our data and equations (1) and (3), but neither is a good fit. The major discrepancies are overestimation of both eddy coefficients at the velocity maximum (the additive terms are much too large) and underestimation of the increases in K_m and K_h when Ri drops below 0.25. A plot of K_m and K_h as functions of Ri shows that they rise abruptly by about a factor of 10 when Ri approaches 0.25. Because a large section of the mixing region is in this Richardson number range, improving this part of the parameterization is particularly important.

Until the diurnal cycle is understood, these parameterizations, which are based on only the large-scale profiles, must be viewed as tentative. If fluctuating internal wave energy or the absorption of solar energy has a major role, a simple Ri parameterization will be inadequate. Discovery of the diurnal cycle also raises the possibility of an annual cycle, because the intensity of the diurnal cycle may vary with season.

We thank Captain Clappitt and the officers and crew of the RV *Thomas G. Thompson* for their cooperation at sea and Wayne Nodland, Dale Hirt, Earl Krause, Matt Nicholas, Pat McKeown, Steve Sova and Thomas Bongers for careful work in collecting the data, and also David Halpern for examining his previous equatorial shear data. This work was funded by the NSF on grant OCE-8214780, as part of the Tropic Heat Program. School of Oceanography, University of Washington, contribution no. 1597.

Hotspot magmas can form by fractionation and contamination of mid-ocean ridge basalts

Don. L. Anderson

Seismological Laboratory, California Institute of Technology, Pasadena, California 91125, USA

Melts ascending from deep reservoirs and trapped beneath thick lithosphere exchange heat with and partially melt the shallow mantle as they crystallize. Basalts erupting through thick lithosphere are more likely to have experienced deep crystal fractionation and contamination than those at mature spreading centres. Geochemical data for ocean island and other hotspot magmas do not require a primitive or lower mantle source.

MID-OCEAN ridge basalts (MORB) are the most depleted (low concentrations of large-ion lithophile (LIL) elements, low values of Rb/Sr, Nd/Sm, $^{87}\text{Sr}/^{86}\text{Sr}$, $^{144}\text{Nd}/^{143}\text{Nd}$, $^{206}\text{Pb}/^{204}\text{Pb}$) and the most voluminous magma type. They erupt through thin lithosphere and have apparently experienced some crystal fractionation before eruption. Isotope ratios show that the MORB reservoir was outgassed and depleted more than 10^9 yr ago. There is growing evidence that there is also an ancient enriched reservoir in the mantle and that the continental crust is not the only complement to the MORB reservoir¹⁻⁴. The most enriched mantle magmas are lamproites, kimberlites, and basalts from islands such as Kerguelen, St Helena and Tristan da Cunha. There is a complete spectrum of basalts lying between these extremes. The presence of ^3He in MORB and the fact that its $^3\text{He}/^4\text{He}$ is higher than atmospheric^{5,6} suggests that outgassing was not 100% efficient, or that MORB is contaminated. Pb isotopes suggest that MORB has experienced some contamination before eruption⁷. Therefore, MORB itself may be a hybrid magma.

The geochemistry of various magma types requires at least two distinct reservoirs in the mantle. The relatively uniform depleted mantle (DM) suffered an ancient depletion event, presumably by removal of a residual fluid. The other reservoir, which we call enriched mantle (EM), is less homogeneous and is presumed to provide the enriched signature of hotspot magmas. Correlated LIL and isotope variations in mantle magmas are often explained by mixing of material from the EM and DM reservoirs.

Basalts with high Rb/Sr, La/Yb and Nd/Sm ratios generally have high $^{87}\text{Sr}/^{86}\text{Sr}$ and low $^{143}\text{Nd}/^{144}\text{Nd}$ ratios. These can be explained by binary mixing of depleted and enriched magmas or by mixtures of a depleted magma and a component representing varying degrees of melting of an enriched reservoir⁷. The variable LIL ratios of such an enriched component generate a range of mixing hyperboles or 'scatter' about a binary mixing curve, even if there are only two isotopically distinct end members. Thus a model with two isotopically distinct reservoirs can generate an infinite variety of mixing lines⁷. In some regions, however, the inverse relationship between LIL and isotope ratios cannot be explained by binary mixing⁸⁻¹³. These regions are all in midplate or thick lithosphere environments and sublithospheric crystal fractionation involving garnet and clinopyroxene might be expected before eruption.

The wide range of isotope ratios in island and continental basalts has led to the view that the mantle is heterogeneous on all scales. The failure of simple binary mixing to explain the spread of isotope and trace element ratios, and the presence of LIL-enriched basalts with time-integrated depleted isotope ratios, has also given rise to the concept that recent mantle metasomatism has affected the source region and may even be a prerequisite for magmatism¹⁴.

Some of the observations which have been interpreted in terms of metasomatism, or an extremely heterogeneous mantle are: (1) scatter of $^{143}\text{Nd}/^{144}\text{Nd}$ - $^{87}\text{Sr}/^{86}\text{Sr}$ values about the mantle array; (2) lack of correlation between $^{87}\text{Sr}/^{86}\text{Sr}$ and $^{206}\text{Pb}/^{204}\text{Pb}$

or $^4\text{He}/^3\text{He}$; and (3) inverse correlations between La/Ce or Rb/Sr and $^{87}\text{Sr}/^{86}\text{Sr}$. However, if one or both end members of a hybrid is a fractionated melt, or represents varying degrees of partial melting, then these observations do not necessarily require multiple sources. If melts from one reservoir must traverse the other reservoir on their way to the surface there is no need for a 'plum pudding' mantle or recent metasomatism of the source.

The cases where a depleted magma causes variable degrees of melting of an enriched reservoir or an undepleted magma partially melts a depleted layer have already been treated^{7,8}. We now treat a fractionating depleted magma interacting with an enriched reservoir. As a point of reference, we consider the depleted magma from DM to be the parent of MORB. If this magma is brought to a near-surface environment it may fractionate olivine, plagioclase and orthopyroxene. If arrested by thick lithosphere it will fractionate garnet (gt) and clinopyroxene (cpx). We assume that the fractionating crystals and melt are in equilibrium. We emphasize varying degrees of crystal fractionation but our results are applicable to the case where the depleted component represents varying degrees of partial melting⁸ of a gt- and cpx-rich region, such as garnet pyroxenite lower oceanic lithosphere, or an eclogite slab.

There are two situations that have particular relevance to mantle-derived magmas. Consider a 'normal' depleted mantle magma. If it can rise unimpeded from its source to the surface, such as at a rapidly spreading ridge, we have a relatively unfractionated, uncontaminated melt, that is, MORB. Suppose now that the magma rises in a midplate environment, and its ascent is impeded by thick lithosphere. The magma will cool and crystallize, simultaneously partially melting or reacting with the surrounding shallow mantle. Thus, crystal fractionation and mixing occur together, and the composition of the hybrid melt changes with time and with the extent of fractionation. Fractionation of gt and cpx from a tholeiitic or picritic magma at sublithospheric depths (>50 km) can generate alkalic magmas with enriched and fractionated LIL patterns. We investigate the effects of combined eclogite fractionation (equal parts of gt and

Table 1 Parameters of endmembers

	Depleted mantle 1	Enriched mantle 2	Enrichment ratio
$^{87}\text{Sr}/^{86}\text{Sr}$	0.701, 0.702	0.722	Sr_2/Sr_1 13.8
ϵ_{Nd}	24.6	-16.4	Nd_2/Nd_1 73.8
$^{206}\text{Pb}/^{204}\text{Pb}$	16.5, 17.0	26.5	Pb_2/Pb_1 62.5

La/Ce	0.265	0.50	Ce_2/Ce_1 1 65
Sm/Nd	0.50, 0.375	0.09, 0.139	
Partition coefficients			
Rb	0.02	Sr 0.04	La 0.012
Ce	0.03	Nd 0.09	Sm 0.18
Pb	0, 0.002	He 0.50	

Fig. 1 La/Ce versus $^{87}\text{Sr}/^{86}\text{Sr}$ for the fractionation-contamination model, compared with Hawaiian basalts. Unfractionated MORB has La/Ce = 0.265. La/Ce of the depleted endmember increases as crystal fractionation proceeds. The enriched endmember has La/Ce = 0.5, in the range of kimberlitic magmas. The Hawaiian tholeiites can be modelled as mixes ranging from pure MORB plus 2–7% enriched component to melts representing residuals after 95% cpx plus gt crystal fractionation and 5–8% enriched component. Alkali basalts involve more crystallization and more contamination. In all the figures, solid curves are mixing lines between EM and melts representing fractionating depleted magmas. Dashed curves are trajectories of constant mixing proportions. Data from ref. 8.

cpx) and 'contamination' on melts from DM. 'Contamination' is modelled by mixing an enriched component with the fractionating depleted magma. This component is viewed as a partial melt generated by the latent heat associated with the crystal fractionation. The assumed geochemical properties of the endmembers, the enrichment factors of the elements in question and the partition coefficients, D , assumed in the modelling are given in Table 1. D for Rb, Sr, Sm, Nd, La and Ce are the mean for cpx and gt¹⁵. Later we shall discuss Pb and He and, in these cases, D is an adjustable parameter. The figures show various ratios for mixes of a fractionating depleted melt and an enriched component (EM). I assume equilibrium crystal fractionation as appropriate for a turbulent or permeable magma body, and constant D . I will not attempt to fit the data displayed in the figures. My purpose is simply to show the range of parameters required to span the data by the proposed mechanism. I do not rule out other contributions to the geochemical complexity of magmas. In particular, I shall discuss the heterogeneity of EM.

La/C versus $^{87}\text{Sr}/^{86}\text{Sr}$

La/Ce is high in melts relative to crystalline residues containing gt and cpx. It is low in depleted reservoirs and high in enriched reservoirs. Low and high values of $^{87}\text{Sr}/^{86}\text{Sr}$ are characteristics of time-integrated depleted and enriched magmas, respectively. As high $^{87}\text{Sr}/^{86}\text{Sr}$ implies a time-integrated enrichment of Rb/Sr, there is generally a positive correlation of Rb/Sr and La/Ce with $^{87}\text{Sr}/^{86}\text{Sr}$. Some magmas⁹, however, exhibit high La/Ce and low $^{87}\text{Sr}/^{86}\text{Sr}$. This cannot be explained by binary mixing of two homogeneous magmas.

On a theoretical La/Ce versus $^{87}\text{Sr}/^{86}\text{Sr}$ plot (Fig. 1) the mixing lines between the crystallizing MORB and EM components reverse slope when MORB has experienced slightly more than 99% crystal fractionation. The relationships for equilibrium partial melting and equilibrium, or batch, crystallization are, of course, the same. Therefore, large degrees of crystallization of a MORB-like melt or small amounts of partial melting of a MORB layer are implied by an inverse relationship between La/Ce (or Rb/Sr, La/Yb, Nd/Sm, and so on) and $^{87}\text{Sr}/^{86}\text{Sr}$ (or $^{144}\text{Nd}/^{143}\text{Nd}$) such as observed at many mid-plate

Fig. 2 ϵ_{Nd} versus $^{87}\text{Sr}/^{86}\text{Sr}$ for mixtures involving a depleted magma or residual fluids from such a magma after crystal fractionation, and an enriched component (EM). Data from various sources including refs 4, 38–44.

Fig. 3 $^{143}\text{Nd}/^{144}\text{Nd}$ (relative to primitive mantle) versus Sm/Nd for mixtures of enriched mantle and residual melts resulting from high-pressure crystal fractionation of MORB-like depleted magma. Data from refs 8, 15, 38–40. See ref. 45 for supporting evidence for Iceland.

environments. The apparently contradictory behaviour of magmas with evidence for current enrichment and long-term depletion is often used as evidence for 'recent mantle metasomatism'. Figure 1 illustrates an alternative explanation. Note that, with the parameters chosen, the Hawaiian alkalis have up to 10% contamination by the enriched component.

ϵ_{Nd} versus $^{87}\text{Sr}/^{86}\text{Sr}$

Isotope ratios for ocean island and continental basalts are compared with mixing curves in Fig. 2. These basalts can be interpreted as mixes between a fractionating depleted magma and an enriched component. The value for primitive mantle ($\epsilon_{\text{Nd}} = 0$) is also shown. The primitive mantle value of $^{87}\text{Sr}/^{86}\text{Sr}$ is unknown and cannot be inferred from basalts that are themselves mixtures. For example, the basalts cover a field extending from 0 to 99.9% crystal fractionation and the corresponding $^{87}\text{Sr}/^{86}\text{Sr}$ ratios at $\epsilon_{\text{Nd}} = 0$ range from 0.7043 to 0.7066. The extreme situations, constant degree of fractionation combined with variable contamination, and constant mixing proportions combined with variable fractionation, can each explain the trend of the data. Together, they can explain most of the dispersion of the data.

Fig. 4 $^{87}\text{Sr}/^{86}\text{Sr}$ versus $^{206}\text{Pb}/^{204}\text{Pb}$ trajectories for mixtures of a fractionating depleted MORB-like magma and an enriched component. Mixing hyperboles are solid lines. Hawaiian basalts fall in the region of 50–99% crystal fractionation (garnet plus clinopyroxene) and 10–30% contamination (EM). Data from various sources including refs 23, 46–49.

ϵ_{Nd} versus Sm/Nd

The mixture-fractionation curves for this system are shown in Fig. 3. High Sm/Nd basalts from Iceland, Hawaii, Siberia, Kerguelen and Brazil all fall near the curve for unfractionated MORB with 1–5% contamination. Alkalics from large oceanic islands with thick crust (Hawaii, Iceland and Kerguelen) are consistent with large amounts of crystal fractionation and moderate (5–10%) amounts of contamination.

The interpretation is that the more voluminous tholeiites comprise slightly fractionated and contaminated MORB, while the alkalics have experienced sublithospheric crystal fractionation and contamination before eruption. MORB itself has ~1% contamination, similar to that required to explain Pb isotopes⁷. The Hawaiian tholeiites can be modelled as MORB that has experienced variable degrees of deep crystal fractionation (0–95%), mixed with 1–5% of an enriched component. The alkali basalts represent greater extents of crystal fractionation and contamination. The Columbia River basalts can be interpreted as MORB which has experienced 80% crystal fractionation and 5% contamination.

Lead and helium isotopes

Rb, Sr and the light rare earth elements (REE) are classic incompatible elements and the effects of partial melting, fractionation and mixing can be explored with some confidence. Relations between these elements and their isotopes should be fairly coherent. Some enriched magmas also have high $^3\text{He}/^4\text{He}$, $\delta^{18}\text{O}$ and $^{206}\text{Pb}/^{204}\text{Pb}$. These isotopes provide important constraints on mantle evolution, but they may be decoupled from the LIL variations and are usually assumed to be so. $^3\text{He}/^4\text{He}$ depends on the outgassing and magmatic history of the depleted reservoir and the U and Th content and age of the enriched component. $^{206}\text{Pb}/^{204}\text{Pb}$ and $^3\text{He}/^4\text{He}$ are sensitive to the age of various events affecting a reservoir because of the short half life of U. The U/Pb ratio may be controlled by sulphides and metals as well as silicates. Nevertheless, it is instructive to investigate the effects of contamination and fractionation on these systems to seek out what other effects or components are involved.

There is no simple relationship between the Sr and Pb isotopes in mantle magmas. A minimum of three components is required to satisfy both isotope systems when only simple mixing is considered. St Helena, for example, has high $^{206}\text{Pb}/^{204}\text{Pb}$ –low $^{87}\text{Sr}/^{86}\text{Sr}$, Kerguelen has high $^{87}\text{Sr}/^{86}\text{Sr}$ –low $^{206}\text{Pb}/^{204}\text{Pb}$, and MORB has low $^{87}\text{Sr}/^{86}\text{Sr}$ –low $^{206}\text{Pb}/^{204}\text{Pb}$. The Pb isotopes in MORB are higher than expected for a primitive or depleted

Fig. 5 Mixing curves for $^3\text{He}/^4\text{He}$ versus $^{87}\text{Sr}/^{86}\text{Sr}$. Two choices for the depleted endmember are shown. Hawaiian basalts imply 90 to >99% crystal fractionation and 5–18% contamination. To make Iceland consistent with Fig. 3, one could raise Sm/Nd (DM) or R_a (EM). Data from refs 50–53.

reservoir. Figure 4 shows a mixing-fractionation curve for $^{87}\text{Sr}/^{86}\text{Sr}$ and $^{206}\text{Pb}/^{204}\text{Pb}$. To span the data, with only two distinct endmembers, it has to be assumed that the partition coefficient for Pb is much less than that for Sr. This would be the case if Pb is entirely contained in low-melting-point phases or is much more incompatible in gt and cpx than is Sr. Figure 4 shows that the data can be explained with only two isotopically distinct mantle reservoirs. However, even if EM is global it can have variable $^{206}\text{Pb}/^{204}\text{Pb}$ and $^{207}\text{Pb}/^{204}\text{Pb}$ as these are sensitive to the U/Pb ratio and the age of enrichment events. U/Pb and $^3\text{He}/^4\text{He}$ of EM will change locally by the subduction of sediments and oceanic crust and by the insertion of basalts which do not make their way to the surface. Isotope ratios of Pb and He, therefore, are variable and change rapidly with time. The various contributions to the enrichment process (subduction, trapped magmas) make it likely that EM, the shallow mantle in our case, is laterally inhomogeneous.

Mid-ocean ridge tholeiites¹⁶ average about 8.5 times the atmospheric ratio (R_a) for $^3\text{He}/^4\text{He}$. Samples from Hawaii^{17,18} have R_a up to 37 and natural diamonds^{19,20} range up to 280. $^3\text{He}/^4\text{He}$ near Iceland and Hawaii can be modelled as two-component mixtures with MORB and Loihi being the endmembers. Other islands have lower ratios than MORB, suggesting a third component, a variably outgassed EM or reduction in $^3\text{He}/^4\text{He}$ by U–Th decay. The high $^3\text{He}/^4\text{He}$ of some ocean island basalts is often assumed to require decoupling from other processes and a lower mantle origin.

Results are shown in Fig. 5. The highest $^3\text{He}/^4\text{He}$ samples from Loihi imply ~18% of the enriched endmember ($R_a = 150$) and >99% crystal fractionation. Prince Edward and Jan Mayan can be modelled as mixtures involving nearly unfractionated MORB. Basalts from Tristan and Gough may require a third component, such as subducted sediments, or they may have evolved in a high U–Th environment. To cover the total range with the chosen endmembers, it is necessary to assume that the He abundance in EM is about twice the abundance in the depleted magma and that D for He is much greater than that for Sr. The partition coefficient for He is unknown, but it may not behave as a classic incompatible element. Clinopyroxene-melt 'partition' (or 'trapping') coefficients for Ar and Kr are 0.2–0.5, and may increase with decreasing atomic weight²⁰. These surprisingly high values are of the order required to explain the He–Sr isotope results. The distribution of $^3\text{He}/^4\text{He}$ in the enriched reservoir is likely to be uneven because it depends on the amount of trapped ^3He , the U and Th content, and the age of enrichment. If part of the LIL enrichment is due to reinjection of oceanic crust and sediments, this part of EM will have a low

$^3\text{He}/^4\text{He}$ ratio. Ancient enriched reservoirs will have higher $^{206}\text{Pb}/^{204}\text{Pb}$ and lower $^3\text{He}/^4\text{He}$ ratios than equivalent modern reservoirs. Nevertheless, combined crystal fractionation and contamination, using only two endmembers, can explain much of the range and several of the trends observed in oceanic basalts.

Discussion

Chen and Frey⁸ propose a model for Hawaiian volcanism that involves melting of an enriched mantle plume from the lower ('primitive') mantle. This upwelling plume traverses a depleted (MORB) region, which partially melts (0.05–2.0%); these melts mix in varying proportions to form the spectrum of basalts found in Hawaiian volcanoes. With their choice of endmembers the MORB component must be small, <2%.

Our results suggest an alternative explanation. Melts from DM rise to the base of the lithosphere, fractionate and mix with melts from EM. At mid-ocean ridges the lithosphere is thin, crystal fractionation occurs at shallow depths, and eruption occurs with little contamination. Mid-plate volcanism involves crystal fractionation at greater depth, >60 km. Because of slower cooling at depth, there is more chance for mixing with melts from the asthenosphere and lithosphere before eruption. Thus, diapirs from the depleted reservoir may be the precursors for both mid-ocean and mid-plate volcanism, but the trace-element and isotope spectra of basalts depend on the thickness of the lithosphere or crust. Material from DM, which initiates melting in the shallow enriched reservoir, dominates the mix. The choice of a single EM component is simplistic but it illustrates the mechanism. On their ascent, MORB diapirs can interact with asthenosphere, oceanic or continental lithosphere, sediments, sea water and subducted material.

In the Chen–Frey mode, the amount of the MORB component decreases as the inferred degree of partial melting of the MORB source increases, the reverse of what might be expected. The relative portions of the MORB and enriched components are also the reverse of what the $^3\text{He}/^4\text{He}$ data indicate. Kaneoka²¹ suggests that the MORB component of Hawaiian basalts represents more than 50–70%. In the present model, the amount of contamination increases as crystal fractionation proceeds.

Kaneoka²¹ favours a model in which LIL- and ^3He -rich material from a deep primitive mantle reservoir rises through and mixes with a shallow, depleted region. He argues that if the enriched layer is shallow, plumes should originate at shallow depth, and the only overlying depleted layer is the oceanic lithosphere. However, the distinctive geochemical signature of hotspot basalts may be acquired at shallow depths, and most of the erupted material may be depleted basalts rising from greater depth. Continental contamination is an oft-invoked mechanism of this type, although it does not work for the rare gases. An LIL- and ^3He -rich shallow mantle does not imply that plumes originate at shallow depth. In discussions of hotspots, it should be recognized that the source of the heat, the source of most of the magma and the source of the isotope signatures may be at different depths. Hot regions of the lower mantle, for example, can localize melting in the transition region (400–650 km depth) and depleted melts from this region may become contaminated as they rise. Melts trapped in, or rising through, the shallow mantle may be responsible for the distinctive physical properties of the low-velocity zone and asthenosphere. Most workers assume that noble gases are strongly partitioned into melts which then efficiently lose these gases to the atmosphere. Outgassing, however, probably occurs only at relatively shallow depths, where the major gases, such as CO_2 and H_2O , can exolve²². If melts are trapped at depth, the noble gases will be as well. The presence of ^3He and ^{36}Ar in magmas does not require the existence of a previously unmelted or primitive reservoir. The $^3\text{He}/^4\text{He}$ characteristics of hotspot magmas, therefore, do not require an explanation separate from that for the other isotopes, except that $^3\text{He}/^4\text{He}$ can decrease rapidly with time in a high-U reservoir.

The magnitude of tholeiitic volcanism, the dominance of the MORB component in mantle magmas and the close temporal

and spatial relationship of depleted and more enriched and evolved alkalic magmas support a controlling role for melts from DM in mantle magma genesis. I propose that oceanic ridges, islands and seamounts share a common source and that mantle magmas differ primarily because of different degrees of sublithospheric crystal fractionation and contamination, and the nature of the (minor) enriched component. Shallow fractionation, crustal contamination, alteration and recycling, will be superimposed on the effects considered here. There is also the possibility that EM is inhomogeneously enriched or veined. Pb isotopes, for example, require more than two endmembers²³. These may differ in age or intrinsic chemistry, or both.

The location of EM, the source of the contamination discussed here, cannot be settled by petrological and geochemical arguments alone. It has been a common, but unfortunate, practice in the recent geochemical literature to avoid the issue by using the terms lower mantle, primitive mantle, undegassed mantle, plume reservoir and ocean island reservoir, interchangeably. The similarity in trace-element and isotope geochemistry between large islands, seamounts, continental rifts and island arcs suggests that EM is widespread and shallow. The most enriched magmas, kimberlites, appear to originate at a depth of ~200 km. Mid-ocean ridges can be traced by seismic means to depths >200 km, in some cases, >400 km (refs 24, 25). The ascent phase of a deep diapir is characterized by melting. Crystallization is caused by entry of the diapir into the cold surface boundary layer. The heat of crystallization causes melting, or wall-rock reactions, and, hence, crystal fractionation and contamination are concurrent processes. The adoption of a single-stage process involving two isotopically distinct endmembers, only one of which is allowed to fractionate, is clearly an oversimplification. The enriched component may represent variable degrees of partial melting of an enriched region which is probably inhomogeneous. The shallow mantle is periodically replenished with subducted material and trapped magmas. Some of these processes serve to diminish the extreme amount of crystal fractionation implied by the present calculations, as can non-Henry's Law behaviour^{26,27}. The possibility of large amounts of eclogite or clinopyroxene fractionation has been discussed by O'Hara²⁸ and others^{29–36}.

There are several mechanisms by which EM might be formed: (1) Melts removed from DM are distributed between the crust and the shallow mantle. (2) Reinjection of sediments and crust (recycling). In both cases, EM is expected to be shallow. The melt and crustal extraction processes are not 100% efficient; thus, LIL-rich melts are trapped in the shallow mantle. Sediments and altered oceanic crust, the top part of the subducted system, are exposed to high temperatures and stresses so they may dehydrate, melt and be scraped off at shallow depths. This component is low in ^8He .

A thin, shallow layer is unlikely to be globally homogenized by plate tectonic processes. The large-scale isotope anomaly in the Southern Hemisphere mantle³⁷ may have been the locus of ancient subduction, just as the circum-Pacific belt is today or the circum-Pangea belt was in the Cenozoic. In this case the Dupal³⁷ anomaly would be due to an ancient subducted component in the shallow mantle (high ^{87}Sr , ^{206}Pb , ^4He). Such an anomaly would be smeared out in time, in the direction of mantle flow, but would diffuse only slowly across the upwellings and downwellings which separate upper mantle convection cells, particularly if it is embedded in buoyant material such as harzburgite.

Note that my model contradicts conventional views of hotspot petrogenesis. The enriched reservoir is shallow rather than deep and it may be relatively infertile, that is, low in CaO and Al_2O_3 . Being shallow it can collect volatiles and LIL by subduction and by trapping of fluids rising from below. Although global it is unlikely to be homogeneous. It protects the deeper, depleted but fertile (low LIL, high CaO and Al_2O_3) reservoir from contamination. It is usually assumed that the source of heat, the source of the basalts and the source of the hotspot geochemical signatures are all the same. The relative stationariness of hot-

spots, the associated swells and high geoid may be due to increased melting in the upper mantle caused by locally high lower mantle temperatures rather than transfer of material from the lower mantle to the surface. It is the thickness of the lithosphere that controls the geochemical signature of intraplate volcanics, not the ease of communication to the lower mantle.

The lower mantle, other than being a source of heat, may not be involved at all in petrogenesis.

Expression of a foreign gene in myeloid and lymphoid cells derived from multipotent haematopoietic precursors

Gordon Keller*, Christopher Paige*, Eli Gilboa† & Erwin F. Wagner‡

Bone marrow cells infected with retroviral vectors carrying the bacterial neomycin resistance (neo) gene as a marker were used for long-term reconstitution of the haematopoietic system of irradiated mice. The neo gene is expressed in the myeloid and lymphoid lineages of these animals and an analysis of the sites of viral integration indicates that these lineages are derived from the same primitive multipotent cells.

THE transfer of foreign genes with retroviral vectors to precursors of the haematopoietic system provides a unique opportunity to analyse the expression and function of a variety of different genes in a well-characterized developmental system that can be manipulated both *in vitro* and *in vivo*. In addition, the proviral integration site can be used as a clonal marker for identifying haematopoietic precursors and for following their progeny through differentiation. This is of great interest as our knowledge of the structure of the haematopoietic system, particularly the relationship of the lymphoid lineages to one another or to the other (myeloid) blood cell lineages, is still incomplete. Colony assays have defined a variety of different precursors, including those which are pluripotent, oligopotent and unipotent for the myeloid lineages¹⁻⁵. However, demonstration of the more primitive precursors capable of generating both lymphoid and myeloid progeny, as well as of precursors restricted to the lymphoid lineages, has been more difficult.

Unique chromosome marker experiments⁶⁻⁸ and embryo reconstitution studies⁹ in the mouse as well as isoenzyme analysis in patients suffering from chronic myelogenous leukaemia

(CML)¹⁰ all support the concept of a common precursor for the lymphoid and myeloid lineages. At present, only one report has provided evidence for the existence of long-lived precursors restricted to the T-cell lineage⁸. Precursors committed to the B-cell lineage or lymphoid precursors common to both the B- and T-cell lineages have not yet been described.

Retroviral vectors will be useful for both gene expression and lineage analysis studies, provided that they can infect all classes of precursors and that the transferred genes can be expressed in the progeny of the infected cells. In the present report, retroviral vectors were used to transfer the neomycin resistance (*neo*) gene to a variety of haematopoietic precursors, including those capable of participating in long-term reconstitution of irradiated mice. Expression of the introduced *neo* gene was demonstrated in the different blood cell lineages of all recipients analysed. Unique viral integration sites in the DNA of different tissues, purified cell populations and cloned T- and B-cell hybridomas showed that multipotent precursors capable of generating both lymphoid and myeloid progeny were infected with the recombinant vectors.

Infection of bone marrow cells

In order to achieve a high efficiency of retrovirus infection, the protocol shown in Fig. 1 was developed. The structure of the retroviral vectors (N2 and N3) used for infection is shown in Fig. 2a. N2 was generated helper-free, whereas N3 contains helper virus (Moloney murine leukaemia virus, M-MuLV). The essential features of the protocol include a 24-h co-culture of the bone marrow cells with the virus-producing cells, followed by a 48-h preselection step that enriches for precursors expressing the *neo* gene. In three separate experiments 50–95% of all colony-forming cells (CFC) survived the 24-h co-culture with the virus-producing cells and of these, 10–20% were able to grow and form colonies in the presence of G418. The frequency of G418-resistant (G418^r) CFC was similar following co-culture with cells producing either N2 or N3 virus. Following the preselection step in liquid culture, 15–50% of the input number

of CFC were recovered. However, a high percentage (60–95%) of these were G418^r.

Reconstitution and analysis

Virus-infected cells from unselected and preselected populations were used to reconstitute irradiated recipients. Myeloid and lymphoid tissues from these mice were analysed at different

Fig. 1 Protocol for viral infection of bone marrow cells. Bone marrow cells from mice treated 5 days earlier with 5-fluorouracil (150 mg per kg body weight) were seeded directly onto a monolayer of irradiated (1,000 R X-ray) virus-producing cells. CBA-HT6T6Bii mice (>10 weeks old), obtained from the Basel Institute for Immunology breeding colony, were used as a source of donor bone marrow in all experiments. The virus-producing cells were maintained in IMDM with 5% FCS and subcultured the day before infection, to achieve 50–80% confluency on the day of the experiment. For co-culture, half of the supernatant was removed and replaced with fresh medium containing the bone marrow cells, polybrene (10 μ g ml⁻¹), conditioned medium from WEHI-3B (D⁻) cells (20%), transferrin (30 μ g ml⁻¹) and BSA (1 mg ml⁻¹). For reconstituted mice 1, 2, 3 and 4, horse serum (15%) and hydrocortisone (10⁻⁷ M) were also included, whereas for mouse 5 these two reagents were replaced by medium conditioned by adherent bone marrow cells. Either 25-cm² flasks containing 2–3 $\times 10^6$ bone marrow cells in a final volume of 4 ml of medium or 75-cm² flasks containing 5–10 $\times 10^6$ cells in 10 ml of medium, were used. After 24 h of co-culture, the bone marrow cells were collected. A sample from this infected population was assayed in methylcellulose cultures to determine the frequency of G418^r CFC (see Table 1). A second sample was injected into irradiated (900R) recipients (CBA/N; >12 weeks old). The remaining cells were selected in G418 (2 mg ml⁻¹) for 48 h before assaying for (1) G418^r CFC and (2) the ability to reconstitute irradiated recipients. This preselection step was carried out on the virus-producing cells for mice 1 and 2, and in the absence of any adherent layer for mouse 5. WEHI-3B (D⁻) conditioned medium was included in the preselection cultures.

Fig. 2 a, Structure of the *neo*-containing retroviruses. The two constructs (N3 and N2) are composed of three parts: (i) the 5'-long terminal repeat (LTR) fragment containing the viral packaging signal (ψ) was derived from M-MuLV small circular DNA by excision with *Bgl*I and *Xho*I, limited exonuclease digestion with *Bal*31 and addition of *Eco*RI linkers (more viral sequences are present downstream from the 5'-LTR' in N2 than in N3); (ii) the bacterial *neo* gene (*Neo*^r) derived from Tn5 by excision with *Bgl*II and *Bam*HI and addition of *Eco*RI linkers; and (iii) a 3'-LTR fragment which was also derived from M-MuLV small circular DNA by excision with *Bam*HI and *Pst*I, followed by *Bal*31 digestion, addition of *Eco*RI linkers and digestion with *Cla*I. The DNA constructs were generated by standard recombinant DNA techniques, and introduced into a thymidine kinase-negative (TK⁻) derivative of NIH 3T3 cells (N3 virus) or into ψ 2 cells²⁴ (N2 virus) by the calcium phosphate precipitation method. NIH 3T3 or ψ 2 cells were selected with G418 (1 mg ml⁻¹) for 8–10 days. NIH 3T3 cells carrying the N3 provirus were subsequently superinfected with M-MuLV helper virus and supernatants from these cells were harvested and used to infect fresh NIH 3T3 cells. Following G418 selection, single clones were isolated, expanded, and used as a source of recombinant virus. N2-transfected ψ 2 cells were also selected in G418 (1 mg ml⁻¹) and single resistant clones were expanded to produce helper-free virus. N3 was produced at a titre of 10⁶ G418^r colony forming units CFU per ml together with 1–2 $\times 10^6$ XC units of helper virus. N2 was produced helper-free at 5 $\times 10^5$ G418^r CFU ml⁻¹. Supernatants from NIH 3T3 cells infected with N2 virus did not contain G418^r CFU (determined by infection of fresh NIH 3T3 cells). When cells were infected with helper M-MuLV, the supernatant contained 10⁵ G418^r CFU ml⁻¹. This assay can detect the presence of one infectious M-MuLV particle in the N2 virus preparation. b, Analysis of intact proviral DNA sequences in spleen cells from mice that had been reconstituted for 12 days with unselected (equivalent of 850 mix-CFC, 15% G418^r) or preselected (equivalent to 170 mix-CFC, >80% G418^r) cells. DNA of high *M*_r was isolated from the spleens of four reconstituted animals and digested with *Sac*I that cuts once in each of the LTRs of the *neo*-containing and helper proviruses and once within the helper virus genome. Equal amounts (10 μ g) of digested DNA were fractionated on agarose gels, transferred to nitrocellulose by the method of Southern¹², and hybridized with a ³²P-labelled U3-specific probe²⁵. This probe detects the diagnostic 3.2-kb fragment of the intact *neo* provirus and a characteristic 5.7-kb fragment from the helper virus genome. The efficiency of bone marrow infection can be estimated from the band intensities by comparison with the cell line Co, which carries only a single copy of the *neo* gene (2 μ g of DNA was loaded in this lane). Spleen DNAs of two mice, reconstituted with unselected cells, are shown in lanes 1 and 2. Lanes 3, 4 are DNAs from those mice, reconstituted with preselected bone marrow cells. c, NPT-II activity from spleen extracts of the four mice described in b. Prior to DNA extraction, the frozen cell pellets (~10⁷ cells) were thawed and lysed in 200 μ l of H₂O. The suspension was centrifuged for 5 min at 10,000 r.p.m. and the aqueous supernatant was used for the NPT-II assay¹¹. Equal amounts of soluble protein were separated in a non-denaturing polyacrylamide gel, which was then overlaid with a 1% agarose gel containing kanamycin sulphate (100 μ g ml⁻¹) and [γ -³²P]ATP (1.5 μ Ci ml⁻¹). The labelled kanamycin sulphate was transferred onto P81 paper which was washed three times (5 min) with hot water (80 °C), dried and exposed on X-ray film. The labelled 29,000-*M*_r band is diagnostic for the NPT-II activity.

times after reconstitution for expression of the *neo* gene. Expression was demonstrated by the presence of G418^r CFC and by the presence of the *neo* gene product, as determined by the neomycin phosphotransferase (NPT-II) assay¹¹. The presence of the intact proviral structure as well as the existence of unique viral integration sites in these mice was analysed in DNA from the different organs (bone marrow, thymus, lymph node, spleen), from purified cell populations and from hybridomas, by Southern blotting¹².

Table 1 Bone marrow cells used for reconstitution of irradiated mice

Mouse	Pre-selected with G418	Total cell no. injected	No. of mix-CFC injected	% G418 ^r mix-CFC
1	+	2.1 × 10 ⁶	1,350	86
1*	—	5.0 × 10 ⁶	750	26
2	+	2.2 × 10 ⁶	8,100	88
2*	—	5.0 × 10 ⁶	2,200	36
3	—	1.0 × 10 ⁶	2,950	25
4	—	1.0 × 10 ⁶	2,950	25
5	+	4.2 × 10 ⁶	23,100	65
5*	—	5.0 × 10 ⁶	1,150	6
5**	—	5.0 × 10 ⁶	1,170	1

Mice 1–4 were reconstituted with bone marrow cells infected with N3 virus whereas mouse 5 received N2(helper-free)-infected bone marrow cells. No viraemia was detected in the sera of mice 1–4 by a sensitive reverse transcriptase assay despite the fact that competent helper virus was present. Mixed colonies were grown from bone marrow cells in 1-ml cultures (35-mm Petri dishes) containing 0.9% methylcellulose in Iscove's modified Dulbecco's medium (IMDM), 5% fetal calf serum (FCS), 10 mg de-lipidated and deionized bovine serum albumin (BSA), 300 µg iron-saturated transferrin, 22.4 µg dipalmitoyl phosphatidylcholine, 23.5 µg cholesterol and 17.3 µg oleic acid. All reagents were prepared as described by Iscove²⁰. DEAE-Sephrose-purified WEHI-3B(D⁺) conditioned medium as a source of multilineage haematopoietic growth factor (MultiHGF/BPA/IL-3)¹⁴ and serum from anaemic mice as a source of erythropoietin²¹ were added in sufficient amounts to give optimal growth of mixed colonies. Conditioned medium from plastic-adherent bone marrow cells was added (10%) as a source of additional growth factors²². G418 was included at 2 mg ml⁻¹ as indicated. Colonies were counted after 9–12 days at 37 °C in a humidified environment of 5% CO₂ in air. Mixed colony-forming cells (mix-CFC) are those precursors that generate colonies containing cells from the erythroid plus at least two other lineages. * Secondary recipient of bone marrow from indicated mice. ** Tertiary recipient. This animal was not healthy at the time of killing. The thymus and lymph nodes were very small and the marrow was somewhat hypocellular. This is not a surprising finding, as it is well known that the reconstituting capacity of bone marrow decreases dramatically with each passage through an irradiated recipient²³.

Short-term reconstituted mice

The efficiency of infection and preselection was analysed in mice reconstituted for 12 days with N3-infected bone marrow cells. Spleens from both groups contained large numbers of macroscopic colonies. Methylcellulose cultures showed a higher frequency of G418^r CFC in the spleens of mice reconstituted with preselected cells (70%) compared with those that received the unselected population (5%).

To analyse the efficiency of gene transfer and the structure of the provirus, DNAs were prepared from individual spleens of both groups. Southern analysis showed that spleens of mice reconstituted with preselected cells contained more intact *neo*-specific sequences (3.2 kilobases, kb) than DNA from spleens of mice reconstituted with unselected cells (Fig. 2b). Similar amounts of helper virus DNA were found in both groups, although no replicating helper virus was detectable by a reverse transcriptase assay. It is possible that CBA/N mice inhibit viral replication, as others have observed a similar phenomenon (W. Ostertag, personal communication). When cell lysates were tested for an active *neo* gene product, much higher levels of NPT-II activity were found in spleen extracts of mice reconstituted with preselected cells compared with those reconstituted with the unselected population (Fig. 2c).

These findings establish that precursors capable of short-term reconstitution can be infected with the recombinant *neo*-containing virus and can survive the preselection step. In order to establish that primitive precursors capable of long-term reconstitution had been infected with the *neo*-containing virus, we next analysed mice reconstituted for 6–17 weeks. The self-renewal capacity of these precursors was assessed by transferring bone marrow from the primary reconstituted animals (mice 1, 2 and 5) to secondary recipients (1*, 2* and 5*) and in one case to a tertiary recipient (5**). Table 1 lists the different bone marrow populations used for reconstitution.

Long-term reconstituted mice

Expression of the *neo* gene was analysed first in the myeloid lineages by the ability of bone marrow cells from the reconstituted animals to form colonies in methylcellulose cultures containing G418. Independent of the time after reconstitution, all of the animals assayed contained G418^r CFC (Table 2). Those reconstituted with preselected cells had higher frequencies of G418^r CFC (13–37%) than those which received unselected cells (6% and 1% for mice 3 and 4). These findings indicate that the *neo* gene is being expressed in precursors of the myeloid lineages. It is noteworthy that the frequency of G418^r CFC decreased with time in the primary recipient and after transfer of bone marrow to a secondary host (Table 2).

To determine whether or not the *neo* gene was present and expressed in cells of the B-lymphoid lineage, clonable B cells

Table 2 G418-resistant colony-forming cells in reconstituted mice

Mouse	Time of reconstitution (weeks)	Colonies per 10 ⁶ cells						% Total G418 ^r CFC
		-G418			+G418			
		E	Mix	Total	E	Mix	Total	
1	7	220	150	2,470	60	40	780	32
1*	3	—	—	880	—	—	180	21
2	6	490	420	4,150	110	150	1,530	37

4	17	240	470	2,470	2	4	20	1
5	11	310	360	2,370	34	21	305	13
5*	5	125	230	1,425	2	3	19	1
5**	7	130	80	1,900	0	0	3	0.2

Conditions for growth of colonies as described for Table 1. Colonies were classified as follows: E, colonies in which all or nearly all of the cells are erythroid; Mix, mixed colonies containing cells from the erythroid plus at least two other lineages; Total, all colonies in the culture, including E, mix, plus those comprised of mast cells, neutrophils, macrophages and mixtures of these. There were no detectable differences in the appearance of colonies or in the state of maturation of the cells within the colonies in the presence or absence of G418 (2 mg ml⁻¹). The mean numbers of colonies counted in 2–6 replicate cultures are shown. Most long-term reconstituted mice had normal numbers of bone marrow cells (16–36 × 10⁶ cells per two femurs and two tibias). The only exceptions were mice 1* and 5**, which contained 3.0 × 10⁶ and 12 × 10⁶ bone marrow cells respectively.

Fig. 3 Neomycin-phosphotransferase (NPT-II) activity in whole tissue extracts from long-term reconstituted mice. Preparation of tissue extracts and the *in situ* NPT-II assay are described in Fig. 2c. SPL, spleen; BM, bone marrow; THY, thymus; LN, lymph node; approximately five times less protein was loaded onto the LN lane. Animals 1 and 2 were reconstituted with preselected bone marrow cells, whereas mouse 3 received unselected cells. Mice 1* and 2* are recipients of bone marrow from mice 1 and 2 respectively.

(CFU-B), a subpopulation of mature B cells that are able to form colonies *in vitro*¹³, were grown in the presence of G418. Between 1 and 3% of the CFU-B found in the spleens of mice 2, 3, 4 and 5 were G418^r. Only 0.3% of those from mice 1* and 5* were able to grow in the presence of G418. Antibody secretion from cells in these G418^r colonies was demonstrated by their ability to form plaques as monitored by protein A plaque assay¹³.

In addition to growth of cells in G418, *neo* gene expression was monitored by assaying different tissue extracts from the reconstituted mice for NPT-II activity. Both myeloid and lymphoid organs of all long-term reconstituted mice tested expressed NPT-II activity (Fig. 3). As expected, organs from mice reconstituted with preselected cells (mice 1 and 2) contained higher enzyme levels than those from mice reconstituted with unselected cells (mouse 3). The presence of the *neo*-encoded protein in the different organs, together with the ability of the various precursors to grow in cultures containing G418, demonstrates unequivocally that the introduced *neo* gene is being expressed in all haematopoietic lineages.

Cell lineage analysis

The next series of experiments was designed to determine the number and the pattern of viral integration sites in the organs and in individual cell lineages of the reconstituted animals. Assuming that the site of integration of the provirus is random, information obtained from this analysis allows (1) estimation of the number of infected precursors that have participated in reconstitution of the different organs and (2) determination of the differentiation potential and longevity of these precursors.

Mice 1, 1*, 2, 2* and 3. Southern analysis of *Bam*HI-digested DNA from thymus, lymph node, spleen and bone marrow of mouse 1 showed three discrete fragments of 6.8, 9.4 and 16 kb (Fig. 4). These fragments were also present in bone marrow cells from the secondary recipient 1*. This finding suggests that a maximum of three precursors gave rise to the majority of *neo*-containing cells in the different organs of these mice. The intensity of the three bands compared with the intensity of a gene present as a single copy in all cells (hybridoma lanes in Fig. 4) indicates that a high proportion of the cells contain the *neo* provirus. From the presence of the same three bands in the different tissues, we conclude that the infected precursors were multipotent with the capacity to generate cells of the myeloid and lymphoid lineages. Finally, the presence of the same three integration sites in bone marrow of mouse 1*, indicates that this precursor (or precursors) could generate new cells capable of

Fig. 4 Lineage analysis of three long-term reconstituted mice (1, 2 and 4). High-*M*_r DNA was isolated from various tissues, purified cell populations and from B-cell hybridomas and digested with *Bam*HI, which does not cut the proviral genome. Approximately 10 µg of digested DNA was fractionated on agarose gels and analysed by Southern blotting¹² using a *neo*-specific probe. 1* and 2* are recipients of bone marrow from mice 1 and 2. BM, bone marrow; THY, thymus; LN, lymph node; SPL, spleen; T, IL-2-dependent spleen cells; B, surface immunoglobulin-positive (sIg⁺) spleen cells; M, mast cells; a-f, B-cell hybridomas.

Methods. To derive IL-2-dependent cells, spleen cells were first stimulated with concanavalin A (Con A, 48 h) then cultured in medium containing either recombinant IL-2 (Roche) or supernatant from EL-4 cells²⁶ for 1–2 weeks. Over 98% of the cells used for DNA analysis were Thy-1.2-positive as determined by direct immunofluorescence using a labelled monoclonal antibody anti-Thy-1.2 and a fluorescence activated cell sorter (FACS II) for analysis. sIg⁺ cells were obtained following labelling of spleen cells with a fluorescein isothiocyanate-conjugated sheep anti-mouse antibody and sorting on a FACS II. Over 95% of the cells in the sorted population were sIg⁺. Mast cells^{27,28} were derived from bone marrow cells that were grown for more than 3 weeks in the presence of WEHI-3B(D⁺) conditioned medium and G418 (2 mg ml⁻¹). Most cells showed the characteristic granules for mast cells determined by astra blue²⁹ and toluidine blue staining³⁰. B-cell hybridomas were generated by fusion between the nonproducer F0 line and lipopolysaccharide (LPS)-stimulated B-cell blasts. Fusions were carried out 4 days after initiation of *in vitro* cultures with 50 µg ml⁻¹ lipopolysaccharide (LPS). G418 (1–2 mg ml⁻¹) was included on day 2 of these cultures. The LPS blasts were washed and fused according to methods described elsewhere³¹. Established hybridomas were selected for resistance to G418 before DNA analysis.

participating in the reconstitution of a second irradiated recipient. When DNA from the spleen of mouse 1 was digested with a second enzyme (*Hind*III), only three discrete bands were again detected, strongly suggesting that no more than three integration sites were present (data not shown).

DNA from bone marrow of mouse 2 contained at least five distinct integration sites (Fig. 4). On transfer of the bone marrow to mouse 2*, three of the hybridizing bands (5, 9 and 15 kb) were undetectable. Two of the bands found in the DNA of the primary bone marrow could also be found in the DNA from the thymus of mouse 2*. In addition, a fragment of higher relative molecular mass (*M*_r), which was not found in the primary mouse, was also present in the thymus DNA. Only the 12-kb band found in the bone marrow of mouse 2 was present in the DNA of bone marrow cells from mouse 2*. As this 12-kb fragment is also found in the thymus DNA of mouse 2*, it could represent a clone of cells derived from a primitive multipotent precursor. Again, the intensity of the bands in the bone marrow of mouse 2 and the thymus of mouse 2* strongly suggests that the majority of cells in these tissues contain the *neo* gene.

Mouse 3, reconstituted with unselected cells, contained a single integration site in the DNA from bone marrow, thymus, spleen and lymph node (data not shown). Only a small proportion of the cells in this animal had the *neo* gene, as determined by band intensity and colony growth (see Table 2). These

Fig. 5 Lineage analysis of mice 5, 5* and 5**. Southern analysis was carried out as described in Fig. 4 legend. DNA from all tissues, cell populations and hybridomas was digested with *Hind*III, an enzyme that does not cut the provirus genome. In addition, DNA from tissues of mouse 5 was also analysed following *Bam*HI digestion (see upper left-hand corner). Tissues and cell populations are designated as in Fig. 4 except for T, which refers to T-cell hybridomas.

Methods. T-cell hybridomas were generated by fusion between the thymoma BW5147 and spleen cells that had been stimulated with Con A in either the presence or absence of G418. Fusion was accomplished by standard techniques using polyethylene glycol 4000 (Merck) as a fusing agent. The hybridomas were first selected in hypoxanthine/aminopterin/thymidine medium and then in G418 (at least 1 mg ml^{-1} G418). From mouse 5, 8×10^6 cells stimulated without G418 and 3.5×10^6 cells stimulated in the presence of G418 were separately fused with a fivefold excess of BW5147 cells, then distributed into 24-well plates (3×10^5 cells per well). After several weeks all the wells from all the plates contained hybridomas; over 80% of the wells had cells that grew in G418. These G418^r cells were expanded and cloned by limiting dilution. From mouse 5*, 8×10^5 Con A blasts that had been stimulated in the presence of G418 were fused to 4×10^6 BW5147 cells and then seeded into two 24-well plates. This fusion generated six hybridomas, all of which were G418^r.

findings raised the question of whether the gene is present in cells of a number of different lineages or in only a single lineage that is found in all the organs examined. This problem was addressed in the analysis of mouse 4 by expanding cells of specific lineages *in vitro* in the presence or absence of G418 and including these in the DNA analysis.

Mouse 4. Interleukin-2 (IL-2)-dependent cells (T cells), and surface immunoglobulin-positive cells derived from the spleen and B-cell hybridomas were used to analyse the integration sites in the lymphoid lineages. Multilineage haematopoietic growth factor (MultiHGF/BPA/IL-3)¹⁴-dependent mast cells represented the myeloid lineages. A common band of 15 kb was found in the DNA from the thymus, lymph node, IL-2-dependent cells, mast cells and one of the six B-cell hybridomas (Fig. 4); this shows that cells from distinct lineages carry the same integration site and indicates that cells present in each of these populations arose from a common multipotent precursor. A similar interpretation is valid for the 7-kb band which is also present in the myeloid and lymphoid lineages.

Despite the fact that the organ DNAs showed two major integration sites, the cloned B-cell hybridomas exhibited five independent sites (Fig. 5). Only one of the fragments found in the B-cell hybridomas corresponded to the predominant 15-kb fragment found in the DNA from the tissues. Several bands found in other hybridomas corresponded to fainter bands that are visible in the DNA of the tissues, the IL-2-dependent cells and the mast cells. However, at least two could not be detected in the DNA of any cell lines or organs (Fig. 4*d, f*). With this analysis, it is not clear whether the unique fragments in the B-cell hybridomas are also present at low levels in the DNA of

the other lineages or whether they are restricted to the B-cell lineage.

To confirm that cells immortalized as hybridomas were of the B-cell lineage, DNA was next analysed for immunoglobulin heavy-chain gene rearrangements. Each hybridoma contained rearranged alleles and was found to be clonal in this analysis (data not shown).

Mice 5, 5* and 5.** The most detailed lineage analysis was carried out on mice reconstituted with N2-infected bone marrow cells. DNA from the organs, from mast cells and from B- and T-cell hybridomas of mouse 5 was analysed for the presence of unique viral integration sites. A similar analysis was performed with DNA from the organs, from T- and B-cell hybridomas of mouse 5*, and with DNA from the bone marrow and spleen of mouse 5**.

Two common integration sites of 17 and 13 kb were found in *Hind*III-digested DNA from all organs of the three mice (Fig. 5). The intensity of the hybridizing bands found in each of the tissues compared with the intensity of the bands found in the hybridomas suggests that a high proportion of cells are carrying the *neo* gene and are therefore of donor origin. This finding was confirmed by the presence of the T6 chromosome in more than 90% of metaphases from bone marrow cells of mice 5* and 5**. In addition to the two common bands, a fragment of lower M_r (8.4 kb) was found in mast-cell, lymph-node and thymus DNA of mouse 5. This fragment was present at low amounts in DNA from the thymus and spleen of mouse 5*, however, it was not detected in DNA from the spleen and bone marrow of the tertiary recipient (5**). Another integration site of 9.4 kb was found in the thymus of mouse 5, and in the spleen of mouse 5*. Finally, DNA from the mast cells and lymph node of mouse 5 contained fragments of higher M_r that were not detected in any other tissue. When DNA from mast cells, lymph node and thymus of mouse 5 was digested with *Bam*HI, at least four integration sites were found in each. Two of these sites (16 and 11 kb) appear to be common to all tissues and may correspond to the common sites present in the *Hind*III-digested DNA. The additional sites may be restricted to individual lineages.

The initial analysis of a limited number of B- and T-cell hybridomas from mice 5 and 5* is shown in the lower panel of Fig. 5. The two common bands present in the tissues are also found in one B-cell and two T-cell hybridomas from mouse 5 as well as in three T-cell hybridomas from mouse 5*. One of these T-cell hybridomas of mouse 5 contained, in addition, a third integration site of 7.2 kb, which was not detected in any of the tissues. Three other hybridomas of mouse 5 (one B-cell and two T-cell) also contained two sites that seem to be present in the tissues from this mouse. One B-cell hybridoma from mouse 5* had only one of the two common sites. This finding is difficult to interpret without further analysis. A more detailed study of the nature of the integration sites in the B- and T-cell hybridomas of these mice will be published elsewhere.

The presence of the same integration sites in mast cells, in B- and T-cell hybridomas, as well as in different tissues, is the most convincing demonstration to date of the existence of multipotent precursors able to generate myeloid and lymphoid cells. The persistence of integration sites in transfer from the primary to the secondary and tertiary recipients, suggests that the multipotent cell infected originally *in vitro*, exhibited substantial self-renewal capacity.

Discussion

The present report describes an efficient protocol for introducing retroviral vectors carrying a foreign gene into haematopoietic precursors of the mouse as well as the application of this method to cell lineage analysis. The protocol differs from methods used by others^{15,16} in several ways. First, bone marrow from 5-fluorouracil-treated rather than from normal mice was used for infection as it is enriched for primitive precursors¹⁷. Second, a preselection step was included in the protocol to obtain a cell population with a high frequency of infected precursors that were expressing the *neo* gene.

Using this protocol we have demonstrated that multipotent precursors common to the myeloid and lymphoid lineages can be infected with recombinant retroviruses. Furthermore, we have shown by the NPT-II assay and by growth of precursors in G418 that the introduced gene is expressed in all lineages of all reconstituted animals tested. Several other groups have recently described the transfer of genes to bone marrow cells using retroviral vectors^{15,16,18}. However, no-one has shown the infection of primitive multipotent precursors or expression of an introduced gene in distinct myeloid and lymphoid lineages.

From analysis of proviral integration sites we were able to enumerate the numbers of infected precursors which reconstituted each recipient. Through transfer of bone marrow from one recipient to the next, it was possible to estimate the longevity (self-renewal capacity) of such cells. Results from mice 1*, 2*, 5* and 5** indicated that some clones were maintained through transplantation, while others were lost (Figs 4, 5). Those clones that were lost might represent precursors at an intermediate stage of development while those that persisted could have been derived from the most primitive ones exhibiting self-renewal capacity. At least six multipotent precursors were identified in five different mice and four of these demonstrated self-renewal ability (Figs 4, 5). Of equal interest would be the identification of restricted precursors and in particular those restricted to the lymphoid lineages. Clones representing cells that might be restricted to the T-cell lineage are those marked by the 6.5-kb

fragment in the thymus and the 7.2-kb band in one T-cell hybridoma of mouse 5 (Fig. 5). Further analysis of viral integration sites from more reconstituted mice should identify such restricted precursors, thereby allowing a novel approach to studying cell lineage relationships.

In conclusion, we have shown that a foreign gene carried by a recombinant retrovirus can be efficiently introduced into haematopoietic precursors and that this gene is expressed in the progeny of these cells. We have also used the viral integration site as a clonal marker for identifying, enumerating and following the fate of haematopoietic precursors. Through analysis of unique viral integration sites, we have demonstrated unequivocally that cells with distinct lymphoid and myeloid phenotypes arose from a common precursor.

Since submission of this manuscript, Dick *et al.*¹⁹ have published a similar study on the introduction of a selectable gene into haematopoietic cells.

We thank Karin Damlin and Helena Skarvall for technical assistance, William Leiserson for FACS analysis and Dr Michael Julius for helpful advice and for providing IL-2. We also acknowledge Drs Barbara Fagg, Norman Iscove, Rolf Müller, Colin Stewart and Ulrich Rüther for critically reading the manuscript, Marion Kennedy for help in its preparation, and Lynn Gisler and Ines Benner for typing it. E.G. is a recipient of a grant from ACS no. MV116B. The Basel Institute for Immunology was founded and is supported by F. Hoffmann-La Roche Co., Ltd., CH-4005 Basel, Switzerland.

Multiple sclerosis and human T-cell lymphotropic retroviruses

A combination of different types of data suggests that some multiple sclerosis patients respond immunologically to, and have cerebrospinal T cells containing, a retrovirus that is related to, but distinct from, the three types of human T-cell lymphotropic viruses. The role of this virus in multiple sclerosis is uncertain.

ALTHOUGH viral infection has been postulated to play a part in multiple sclerosis (MS), a demyelinating disease of the central nervous system (CNS), there is no formal proof that any virus is involved in the aetiology of the disease. Since the discovery of the first human retroviruses¹, we have become interested in

their role as possible causes of various human diseases, including MS.

MS has some features that are characteristic of autoimmune disease. For example, it is associated with increases in absolute numbers of T cells in the cerebrospinal fluid (CSF)² and

occasionally by disturbances in the relative proportions of T-cell subpopulations during exacerbation or remission of the disease^{2,3}. A high level of oligoclonal immunoglobulin in MS CSF is a characteristic clinical finding⁴, and areas of demyelination in the brain (plaques) are usually associated with mononuclear infiltrates and often occur perivascularly⁵. Some characteristics of human retrovirus infection parallel features of autoimmune disease. The human T cell is the main target of infection of all known human retroviruses. T4-positive (helper-inducer) lymphocytes are transformed by human T-cell lymphotropic virus (HTLV)-I and -II⁶ and are killed by HTLV-III⁷, resulting in subpopulation imbalances. Infections with HTLV-I and HTLV-III have occasionally been associated with polyclonal B-cell activation and immunoglobulin production⁶. Moreover, T cells isolated from CSF of MS patients and maintained in culture closely resemble HTLV-transformed human T cells in their ability to express receptors for interleukin-2 (IL-2) for prolonged periods^{6,8}.

Recently, it was shown that HTLV-III can be detected in the brain⁹ and isolated from CSF and neural tissue of AIDS (acquired immune deficiency syndrome) patients¹⁰. Although the target cells await identification and may be of either neural or haematopoietic origin, the CNS pathology seen in MS involves cells of both lineages.

To study the possible involvement of human retroviruses in MS, we examined two sample populations. The first comes from Sweden, traditionally an area with a high incidence of MS; a recent large study reported an incidence of 5.3 per 100,000, with a female/male ratio of 1.5–1.6 and a peak age of onset of 20–39 yr¹¹. Although there is no evidence for Sweden, the uneven geographical distribution and the increasing prevalence of MS in neighbouring Finland have raised the possibility of a real increase in disease incidence¹². In western Norway, a threefold increase in prevalence from 20.1 to 59.8 per 100,000 was reported for the period 1963–83, reflecting a corresponding increase in incidence of new cases from 1.5 per 100,000 between 1953 and 1962 to 3.5 per 100,000 between 1968 and 1977 (ref. 13).

The second sample population comes from Key West, Florida, which has only recently become a high-risk area. Key West, an island 1.5 × 3.5 miles in size located 156 miles south-west of Miami, has a population of 26,450. Approximately 4,000 individuals are native-born. Although the first case of MS was diagnosed in Key West 57 years ago, it was not until 1981 that an unusual prevalence of the disease was suspected¹⁴.

We have examined the CSF and sera of MS patients from these two populations for the presence of antibodies reactive with antigens of the HTLV family. The availability of CSF T-cell lines from MS patients allowed us to screen for human retroviruses known to be T-lymphotropic by an assay that detects viral RNA in cells in which viral genes are expressed¹⁵.

Swedish patients

We examined paired samples of CSF and serum, in each case obtained on the same day, from 35 Swedish patients with definite MS, based on the criteria of McDonald and Halliday¹⁶. These patients were between 19 and 57 years old when the samples were obtained; 14 were male and 21 were female. The disease duration ranged from 10 days to 21 years (median 8 yr) from initial onset of symptoms. In 15 patients, optic neuritis marked clinical onset of the disease. Four patients were incapacitated, 11 had some symptoms and 20 were able to carry on normal activities. Samples from 15 patients were obtained during exacerbation, which had started between 5 days and 3 months previously. Fourteen other patients were in remission and six patients had progressive disease. One patient was receiving adrenocorticotrophic hormone (ACTH) therapy at the time of sampling and two patients had received ACTH 5 and 6 months before sampling, respectively.

Paired samples of CSF and serum were obtained on multiple occasions during exacerbation, remission and progressive disease from 3 of the 35 patients, who were aged 11, 24 and 34 yr at the onset of disease. This study was limited to three patients

Fig. 1 *a*, Presence of antibodies reactive with HTLV-I p24 *gag* protein (●) and AMV p27 (○) in CSF from Swedish MS patients, patients with other neurological diseases (OND), and normal donors. All samples were tested simultaneously in the same laboratory. Data analysis by the Mann-Whitney *U*-test indicated that the MS CSF samples differed significantly from all OND CSF samples ($P=0.059$) and from OND samples taken from patients with an intact blood-brain barrier ($P=0.002$). *b*, Presence of antibodies reactive with HTLV-I p24 in sera of 35 Swedish MS patients and 43 normal Swedish donors. Serum samples from each group were diluted 1:150 in phosphate-buffered saline (PBS)/1% bovine serum albumin (BSA) and assayed for IgG antibody against HTLV-I p24 by ELISA as described for *a* below. Data analysis by the Mann-Whitney *U*-test indicated that the MS sera differed significantly from the normal sera ($P<0.001$). Results are the mean A_{405} for duplicate determinations.

Methods. *a*, A single CSF sample from each patient was tested by ELISA using 2 $\mu\text{g ml}^{-1}$ p24 or p27 bound to Immulon II plates (Dynatech, Alexandria, Virginia) in carbonate-bicarbonate buffer, pH 9.9. Nonspecific binding was blocked by addition of 1% BSA in PBS. All patient CSF samples were diluted so that the concentration of IgG equalled that found in normal CSF, then applied to the plates. After 1 h at 23 °C, an optimal concentration of peroxidase-conjugated goat anti-human IgG (heavy and light chain; KPL, Gaithersburg, Maryland) was added for 1 h at 23 °C. After extensive washing, the plates were incubated with 2,2-azino-di-(3-ethylbenzthiazoline) sulphate and hydrogen peroxide and the plates read at 405 nm in a Titertek Multiscan (El Fab, Helsinki, Finland). Assay conditions were standardized using HTLV-I and HTLV-III-positive sera and normal control sera. Each assay included serum samples from an HTLV-I leukaemic patient (F0920) as a positive control and NIH HTLV-II-negative sera as a negative control.

because it involves multiple taps to obtain CSF samples in sufficient quantity to perform all assays. One of the patients received ACTH several times during the sampling (see legend to Fig. 3b).

In addition, a single CSF sample was obtained from each of 18 patients with neurological diseases other than MS (OND) and from 7 healthy subjects. As a control, serum samples were also obtained from 80 healthy Swedish hospital staff members and from blood donors.

Single CSF samples from each of 35 Swedish MS patients, 18 OND patients and 7 healthy subjects were evaluated for the presence of antibody reacting with the major core protein, p24, of HTLV-I¹⁷ by enzyme-linked immunosorbent assay (ELISA), as described in Fig. 1 legend. CSF from MS patients had higher levels of the anti-p24 antibody than CSF from normal individuals and from most of the OND patients (Fig. 1a). The three OND CSF samples that were notably reactive with p24

Fig. 2 Comparison of reactivity in ELISA of HTLV-I (a), -II (b) and -III (c) disrupted virions with serum antibodies of 35 MS patients, 10 OND patients and 80 normal blood donors (all Swedish)^{17,18} (●). All samples were tested simultaneously in the same laboratory. Additional tests for specificity of all sera were performed in two ways: (1) by competition assays using extracts of virus-producing cells, phytohaemagglutinin (PHA)-stimulated normal human peripheral blood lymphocytes, and fetal calf serum¹⁹; (2) by using HTLV-III type-specific antibody¹⁷. ▲, Sera were successfully competed in either assay by more than 50%.

were from a Guillain-Barré patient, a patient with meningitis of unknown origin and a patient with lymphocytic meningo-radulitis¹⁸. None of the MS CSF samples showed reactivity with the p27 of avian myeloblastosis virus (AMV) (Fig. 1a), which has low sequence homology with HTLV-I p24¹⁷, demonstrating the specificity of the antibodies for HTLV-I p24. Of the 18 OND samples tested, only the CSF from the meningo-radulitis patient was reactive with AMV p27.

ELISA analysis^{19,20} for HTLV-I p24 antibodies revealed significantly higher levels ($P < 0.005$) of these antibodies in sera from 35 MS patients (mean $A_{405} = 0.746 \pm 0.155$) than in 43 normal sera (mean $A_{405} = 0.325 \pm 0.102$) (Fig. 1b). For comparison, HTLV-I leukaemic serum F0920 routinely showed ELISA reactivity of $A_{405} 1.55-1.57$ in the same assay at the same serum dilution. To determine the specificity of the anti-p24 antibody in these sera, two assays were performed: one used a competitive radioimmunoassay (RIA) and the second a competitive ELISA. HTLV-I- and HTLV-III-positive sera were used to establish effective conditions to compete anti-p24 antibody with

disrupted virions of HTLV-I and of HTLV-III. In competitive-inhibition RIA and ELISA using serum samples from six MS patients, anti-p24 antibodies were completely inhibited by HTLV-I p24 and partially inhibited by disrupted HTLV-I and -III virions but not by AMV p27 (Table 1). In contrast, for serum from an HTLV-I leukaemic patient, anti-p24 antibody was completely inhibited by HTLV-I virions but not by HTLV-III virions.

The sera from the three OND patients whose CSF reacted with HTLV-I p24 also showed reactivity with HTLV-I p24. Whereas the reactivity of the case of lymphocytic meningo-radulitis¹⁸ could be considered nonspecific because the CSF reacted also with AMV p27, the case of Guillain-Barré may be linked with HTLV infection and it would be worthwhile to study more cases of the disease. The third OND case with meningitis of unknown origin could not be classified clinically.

Single serum samples from 35 MS patients, 10 patients with OND and 80 normal blood donors were evaluated by ELISA for reactivity with disrupted virions of HTLV-I, -II and -III²¹ (Fig. 2). The reactivity with HTLV-I of sera from MS patients (mean ratio 1.17) was significantly higher (Mann-Whitney U -test, $P < 0.003$) than that of OND sera (mean ratio 0.59) and of normal sera (mean ratio 0.45, $P < 0.001$). The reactivity of MS sera with HTLV-II (mean ratio 1.63) did not differ significantly from that of OND sera (mean ratio 1.24, $P < 0.08$) but did differ significantly from that of the normal sera (mean ratio 0.87, $P < 0.001$). Serum reactivity for HTLV-III showed no significant differences between all groups. Serum antibody in three MS patients was shown to be significantly inhibited by HTLV-I, -II or -III antigen or by specific antibody (see Fig. 2). No serum from OND or normal individuals was successfully competed with in these assays.

Serial CSF and serum samples from three MS patients, who were seen from the onset of their disease, were tested for antibody reactivity with HTLV-I p24 (Fig. 3). In the case of patient 01-12 (Fig. 3a), both the CSF and serum anti-p24 antibody levels fluctuated markedly between 1982 and 1984. A peak of CSF antibody in February 1983 was accompanied by elevation of the serum antibody, but the peaks of serum antibody observed in August 1983 and December 1984 were not accompanied by a rise in CSF antibodies. All antibody detected was of the IgG class; no IgM antibody was detected. The total IgG concentration in serum and CSF remained unchanged during the observation period (Fig. 3a); thus, the increase in specific antibody could not be explained by polyclonal increases in IgG levels.

In the second MS patient, 20-01 (Fig. 3b), p24 reactivity was detected in serum and CSF samples collected from 1977 to 1982; the two curves are parallel except from November 1981 onwards, when a rise in CSF antibody was accompanied by a decrease in serum antibody. Again, all antibody was IgG; no IgM was detected. The fluctuation in anti-p24 antibody concentration did not reflect changes in CSF and serum IgG levels, which remained relatively constant.

Table 1 Competitive inhibition for HTLV-I p24 antibodies in sera of Swedish MS patients

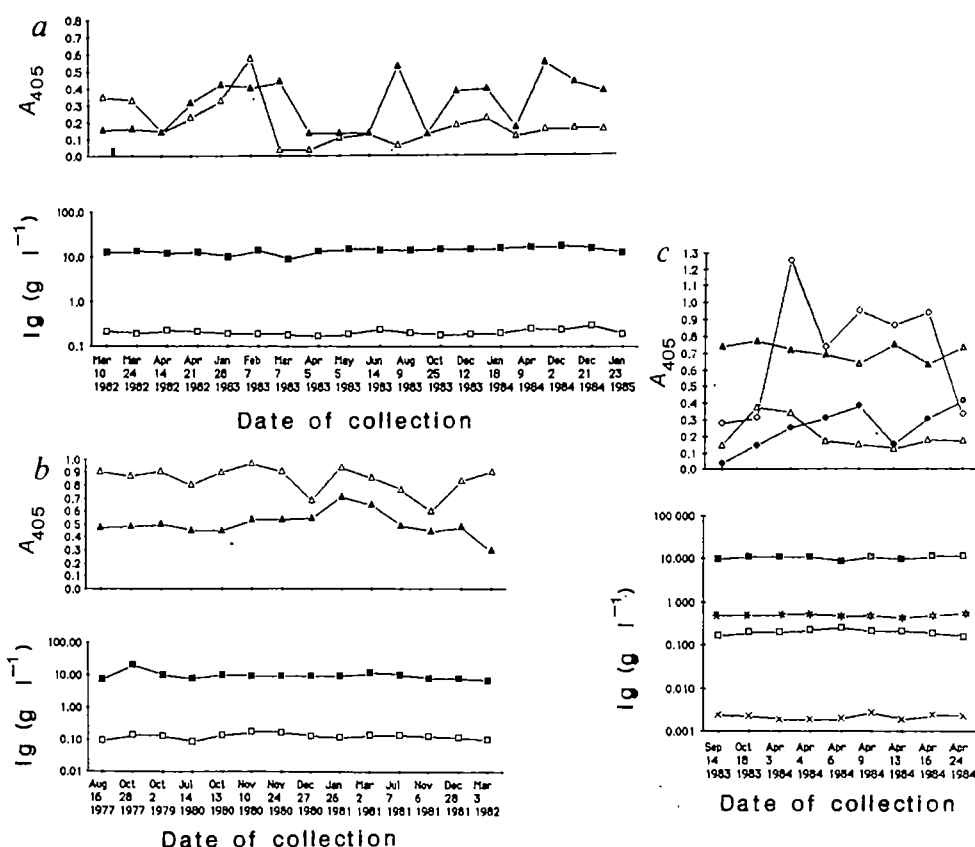

Patient	Competing antigen:			
	Disrupted virions HTLV-I	Disrupted virions HTLV-III	HTLV-I p24	AMV p27
13-10*	46	44	86	6
01-12*	29	30	83	4
3380†	58	51	98	NT
2268†	40	31	83	-8
2167†	61	29	89	NT
1738†	29	15	86	NT
F0920†‡	90	28	94	NT

* Patients' sera were diluted 1:25 and incubated overnight on plates precoated with goat anti-human IgG as a 'catcher' antibody. Inhibition of HTLV-I p24 antibody was determined by reacting various concentrations of disrupted virions of HTLV-I and -III, AMV p27 and HTLV-I p24 with wells containing patients' sera for 3 h at 37 °C. After washing, binding of HTLV-I p24 was assessed by incubating all cells with 0.25 μ g 125 I-labelled HTLV-I p24 (1×10^5 c.p.m. per well). Inhibition is expressed as $[(^{125}\text{I-p24 c.p.m. bound with no competing antigen} - ^{125}\text{I-p24 c.p.m. bound with competing antigen}) / \text{total } ^{125}\text{I-p24 c.p.m.}] \times 100$. Values are the percentage inhibition of $^{125}\text{I-p24}$ binding by 0.5 μ g of competing antigen.

† Specificity of antibodies against HTLV-I p24 in four MS sera was determined by competitive inhibition in an ELISA with soluble HTLV-I p24, disrupted virions of HTLV-I and -III and AMV p27. Equal volumes of patients' sera (1:100 dilution) were incubated with soluble antigen (0.7 μ g ml^{-1}) for 30 min then applied to plates precoated with HTLV-I p24 as described in Fig. 1 legend. Per cent inhibition was calculated as follows: $[(A_{405}$ of sera without soluble competitor $- A_{405}$ of sera with competitor) / A_{405} competition] $\times 100$. NT, not tested.

‡ Serum from an HTLV-I leukaemic patient was diluted 1:500 and inhibitors used at 0.35 μ g ml^{-1} .

Fig. 3 Antibody reactivity with HTLV-I p24 in serial samples of CSF and sera obtained from Swedish MS patients during their disease, compared with concentrations of IgG and IgM in the same CSF and sera. All samples were tested simultaneously in the same laboratory. *a*, Patient 01-12: onset of MS in September 1977 at age 34 yr. The course of the disease was characterized by frequent, acute and short exacerbations, particularly during the study period from 1982 to 1984. The patient received no ACTH or steroid treatment. *b*, Patient 20-01: onset of MS in November 1976 at age 24 yr. The course of the disease was characterized by exacerbations from its onset to 1983, with slow progression of the disease thereafter. The patient received two ACTH treatments in December 1980 and December 1981. *c*, Patient 13-10: onset of MS in March 1976 at age 11 yr with exacerbations in 1979, 1980, April and September 1983, and April 1984, with complete recovery between exacerbations. Patient treated with ACTH only during April 1983, 1 yr before the exacerbation in April 1984. Δ , IgG antibody to HTLV-I p24 in CSF; \blacktriangle , IgG antibody to HTLV-I p24 in sera; \square , \blacksquare : concentration of IgG in CSF and sera, respectively; \times , $*$: concentration of IgM in CSF and sera, respectively.

Δ , IgG antibody to HTLV-I p24 in CSF; \blacktriangle , IgG antibody to HTLV-I p24 in sera; \square , \blacksquare : concentration of IgG in CSF and sera, respectively; \times , $*$: concentration of IgM in CSF and sera, respectively.

Methods. The assay for HTLV-I p24 antibodies was as described in Fig. 1 legend. The immunoglobulin concentrations were determined by an electroimmunoassay described elsewhere²². Serum samples were diluted for the ELISA assay to achieve approximately the same immunoglobulin concentration as found in the CSF samples in order to compare the relative amounts of specific antibody. The immunoglobulin concentrations plotted are therefore those used in the assay.

In the third patient sampled, 13-10 (Fig. 3c), it was possible to follow the anti-p24 antibody levels over several months before and during an acute clinical exacerbation in April 1984. A dramatic rise in CSF anti-p24 antibody of the IgM class was detected between 14 September 1983 and 3 April 1984, accompanied by a lesser but still significant rise in CSF IgG antibody to p24. During April 1984, the CSF IgG antibody decreased to its original value. The CSF IgM antibody levels remained high until 13 April 1984, after which they returned to the levels observed before exacerbation. The concentration of IgM serum antibody fluctuated, whereas that of the IgG serum antibody remained relatively high during the observation period. None of these changes can be explained by concomitant changes in CSF or serum immunoglobulin concentrations, which remained relatively stable during the observation period.

Intrathecal production of immunoglobulin

IgG and albumin concentrations in CSF and serum from the Swedish MS patients were determined²² to obtain the IgG-albumin index (CSF IgG \times serum albumin / serum IgG \times CSF albumin), an indicator of intrathecal immunoglobulin production in CSF²³. Values above 0.66 indicate intrathecal immunoglobulin production in patients with an intact blood-brain barrier²³. For the three patients who were repeatedly sampled, the indices ranged from 0.81 to 6.82, with only two samples showing values <1.00 . For the MS patients in Fig. 1, values ranged from 0.50 to 2.16, with only four values less than 0.66. Thus, a portion of the CSF IgG of these patients is synthesized in the CNS and does not originate in the blood.

The ratio of CSF albumin to serum albumin is taken as an indicator of the integrity of the blood-brain barrier²⁴; this ratio

was within the normal range for all MS patients, indicating an intact blood-brain barrier. However, the three OND patients with high levels of CSF antibody reactive with HTLV-I p24 (Fig. 1a) had ratios of 0.033, 0.020 and 0.011, compared with 0.0074 for normal donors, indicating that the blood-brain barrier was not intact, permitting leakage of serum proteins into the CSF.

Patients from Key West, Florida

At the time of assessment on 1 September 1983, 37 patients with MS were identified in Key West¹⁴. Only one was not Caucasian, and there were two pairs of siblings with MS and two patients with MS-afflicted siblings living elsewhere. The diagnosis of MS was again based on the criteria of McDonald and Halliday¹⁶. Of the 37 patients, 17 were available to us for this study. Five were born in Key West; of the other 12, 5 had moved there at ages of 5–18 yr and 7 at age 22–39 yr. The onset of MS preceded this study by 1–5 yr in 12 patients, by 9 yr in one patient, and by 14, 16, 19 and 20 yr in the remaining patients. Three patients had never received steroid therapy, 13 had received steroid or ACTH therapy (no later than 1983) and one patient was being treated with Immuran at the time of study.

Paired samples of CSF and serum were available from 9 of the 17 patients, and serum samples were available from the remaining 8 patients. A second serum sample obtained 4 weeks later was available from 9 of the 17 patients. Seventeen close contacts of the patients (spouse, parent, sibling) and 17 other individuals also donated blood for this study.

Table 2 shows the number of sera from MS patients and from their contacts that were reactive with HTLV-I p24 and disrupted virions of HTLV-I, -II and -III at one point in time. Seven serum

Fig. 4 Detection of cells expressing RNA with homology to HTLV-I in cultures derived from CSF of MS patients. *a*, Representative field of cultured cells obtained originally from CSF of native-born Key West MS patient no. 4 and hybridized with an HTLV-I 3' probe. This patient showed onset of MS in 1982 at age 21 yr. The disease followed a relapsing-remitting course with accumulated moderate neurological deficits attributed to spinal cord involvement; there was major manifestation of mild to moderate ataxia and spastic paraparesis. Labelled cells were present at a frequency of 0.01%. *b*, Representative field of cultured cells obtained from CSF of a healthy Swedish subject and hybridized with the HTLV-I 3' probe, as described for *a*. No labelled cells present. Pictures of representative fields of cultured cells obtained from two other Key West MS patients and one Swedish patient (see text) were similar to *a*. Scale bar = 10 μ m.

Methods. Freshly isolated CSF cells were co-cultured in cluster plates (Costar) with autologous γ -irradiated peripheral blood mononuclear cells in complete medium containing purified PHA (PHA-P, 1 μ g ml⁻¹; Burroughs-Wellcome) for 3 days. Cell concentrations were adjusted to 2×10^5 ml⁻¹ in complete growth media with 50 ng ml⁻¹ recombinant IL-2 (Sandoz, Vienna, Austria). Cells were maintained in logarithmic growth by periodic supplementation with fresh media containing IL-2 and by stimulation with PHA-P. All cell lines were maintained in the same laboratory before hybridization. *In situ* hybridization was carried out using ³⁵S-labelled RNA probe specific for the 3' region of HTLV-I¹⁵. The RNA probe was transcribed from a full-length genomic clone of HTLV-I and averaged 1–2 kilobases long. Probe was hybridized at $1\text{--}2 \times 10^8$ d.p.m. ml⁻¹ in relaxed conditions (45 °C) and autoradiographed for 4–8 days. All cell lines were hybridized in the same conditions in the same laboratory, and cells were examined using a double-blind code.

samples from MS patients were reactive with HTLV-I, four with HTLV-II and one with HTLV-III; three sera also reacted with HTLV-I p24. Serum of one patient reacted with all three HTLV types, whereas serum of another patient reacted with only HTLV-I and -II. Of the 17 MS sera, 10 were reactive with an HTLV antigen at least once. Of the 17 donors who had intimate contact with the MS patients, two showed serum reactivity with HTLV-III: one of the sera, obtained from a homosexual brother of one of the MS patients, was HTLV-III-seropositive; his serum reactivity might reflect true exposure to the HTLV-III agent of AIDS rather than a cross-reactivity. The second donor was a male not known to be in any HTLV high-risk group. None of the sera from 17 people employed at the hospital where most of the MS cases were treated showed reactivity with HTLV-I, -II or -III.

Of nine CSF samples available from these MS patients, only one sample was reactive with HTLV antigens, specifically with HTLV-I p24. Of the eight negative samples, seven were from patients whose sera were reactive with HTLV antigens.

HTLV-I-related nucleotide sequences

In situ hybridization was used to examine cultured CSF cells obtained from five Key West MS patients, three Swedish MS patients and two healthy Swedish subjects for the presence of HTLV-specific RNA by methods described previously (ref. 15 and unpublished results with M. Feinberg), using specific molecularly cloned HTLV-I and HTLV-III probes. So far, three of the CSF cultures derived from Key West MS patients (who had suffered from MS for 3, 4 and 21 yr) and one CSF culture derived from a Swedish MS case (who had suffered from the disease for 1 month) have shown the presence of labelled cells

following hybridization under low-stringency conditions (45 °C instead of 50 °C) with the HTLV-I 3' RNA probe, which contains predominantly long terminal repeat sequences. These positive cells exhibited an average of 50 grains per cell (Fig. 4*a*) and were observed at a frequency of from 0.001 to 0.01% of the 5×10^5 cells generally examined. In contrast, hybridization of the same HTLV-I probe under identical conditions to cultured CSF cells from two normal individuals consistently failed to reveal labelled cells (Fig. 4*b*); similarly, there were negative results with normal peripheral blood cells, bone marrow and other cell types. Hybridization of an HTLV-I probe specific for the *gag* coding region to CSF cells from two Key West MS patients also revealed rare labelled cells. Thus, cells in four MS CSF cultures contain RNA that hybridizes with HTLV-I under low-stringency conditions. In several experiments in which hybridization was carried out under standard stringency conditions (50 °C), no labelled cells were observed in CSF from one Key West MS patient. Although difficult to quantitate because of the low number of positive cells observed after hybridization at 45 °C, the lack of detectable label under conditions of higher stringency suggests that the RNA detected shares only partial homology with the HTLV-I genome. No hybridization was detected in the same MS CSF cultures using an HTLV-III 3' RNA probe under reduced stringency, indicating a lack of RNA homologous to this virus in the cultured cells.

Discussion

The data presented here indicate the presence of antibodies reactive with HTLV antigens in CSF of Swedish MS patients at concentrations significantly higher than those in CSF samples from Swedish OND patients and from healthy donors. The three OND patients with high CSF levels of anti-HTLV antibodies were shown to have an impaired blood-brain barrier, which suggests that the antibodies were derived from serum. The CSF from seven healthy subjects with intact blood-brain barriers showed no reactivity. Antibodies reactive with HTLV-I p24 antigen (Fig. 1*b*) and with disrupted virions of HTLV-I and -II (Fig. 2) were at higher levels in sera of Swedish MS patients than in sera from OND patients (Fig. 2) or from normal healthy subjects (Figs 1*b*, 2). Perhaps even more significant is the fact that of 17 sera collected from Key West MS patients at various times, 10 reacted at one time or another with an HTLV antigen, whereas reactivity was observed in only 2 of 17 sera obtained from close contacts of the patients (one of whom was a homosexual with serum antibody against HTLV-III) and in none of 17 sera from hospital staff workers from the same area.

One cannot exclude the possibility that, as in the case of measles antibodies in CSF of MS patients²⁵, the HTLV antibodies in CSF represent only a small fraction of the immunoglobulin produced intrathecally by MS patients. Unlike measles antibodies²⁶, however, the level of HTLV antibodies fluctuated in the CSF of MS patients from whom serial CSF samples were available. In one case studied (Fig. 3*c*), a sharp rise of these antibodies accompanied an exacerbation of the clinical disease. It is important, therefore, to emphasize that the antibody reactivity identified in some MS sera or CSF was detected at some periods but not at others.

No uniform response to one particular type of HTLV was observed; this was especially obvious in the Key West MS patients, in whom serum reactivity with any of the three types of HTLV varied among patients. In two cases, the same serum samples reacted with more than one type of HTLV (Table 2). The HTLV-I anti-p24 reactivity in six Swedish MS sera was comparably inhibited by HTLV-I and HTLV-III disrupted virions (Table 1), which may reflect recognition of an epitope(s) on HTLV-I p24 which is shared with other types of HTLV²⁷. The fact that none of the Swedish MS CSF samples reacted with AMV p27, and that 10 HTLV-reactive sera from Key West patients did not react with disrupted virions of visna virus or gibbon ape leukaemia virus indicates that the antibody response of the MS patients is directed specifically towards one or more HTLV-related proteins. But as our data suggest that it is not

Table 2 HTLV-reactivity of sera from Key West patients, intimate contacts and hospital workers

Clinical status	No. of patients	No. of sera reacting with:				No. of positive cases/total*
		HTLV-I p24	HTLV-I	Disrupted virions of HTLV-II	HTLV-III	
MS	17	3	7	4	1	10†/17
Contacts	17	1	0	0	1	2‡/17
Hospital workers	17	0	0	0	0	0/17

Reactivity was determined by ELISA; the results were all confirmed by competition with either antigens of or specific antibodies to HTLV-I, -II and -III¹⁷⁻¹⁹. All samples were tested simultaneously in the same laboratory. The contacts and hospital workers groups were each compared with MS patients using Yates' χ^2 analysis: $\chi^2 = 5.44$ ($P = 0.020$) for contact group; $\chi^2 = 9.67$ ($P = 0.002$) for hospital workers.

* The positive results in the MS patients are transient; they are found at only a specific point in time in any given patient.

† Serum of one patient reacted with all three types of HTLV; serum of another patient reacted with types I and II, and serum of one patient reacted only with HTLV-I p24.

‡ One case was a homosexual brother of an MS patient.

directed exclusively at any of the three known HTLV types, it is difficult to apply the rigid criteria established for evaluation of serological results in diseases linked unquestionably with either HTLV-I (leukaemia, lymphoma) or HTLV-III (AIDS). Indeed, interpretation of serological results in the present study is more arbitrary and the detection of HTLV antibodies should in no way be considered of diagnostic value for MS.

The detection of RNA homologous to HTLV-I in CSF cells of four MS cases whose sera reacted with HTLV-I antigen (Table 2) indicates that a human retroviral genome is being expressed and suggests the possibility that a virus is present. The low frequency of hybridizing cells is similar to the situation observed in primary samples of T cells from HTLV-III-infected patients (AIDS and AIDS-related complex, ARC), where 0.01% or less of cells express RNA¹⁵. The *in vitro* cultivation of T cells infected with HTLV-III results in increased expression of RNA and protein; the actual percentage of cells expressing virus after *in vitro* cultivation is probably related to the frequency of virus-infected cells in the original sample. *In situ* hybridization studies with another retrovirus, visna virus, indicated that fewer than 1% of cells expressing low amounts of viral RNA were found in the tissue samples taken from infected sheep.^{28,29}

As the presence of anti-HTLV antibodies in the CSF of MS patients suggests an antigenic stimulation from the CNS, it seems reasonable to search in the CNS for the presence of the appropriate antigen. The only evidence that the human brain is susceptible to HTLV infection is the detection of HTLV-III in brains of children and adults with AIDS encephalopathy¹⁰. In diseases caused by HTLV, the target for primary virus infection is the peripheral T cell. If the same is true in MS, infected peripheral T cells might transport the virus to the CNS, cells of which might be permissive for viral replication. Damage to myelin-producing glial cells could result directly from viral infection. Whereas no evidence exists for the presence of virions in MS brain, it should be stressed that a specific search for the presence of human retrovirus or its components in brain cells has not yet been made.

The presence of CSF cells that hybridize with the HTLV-I probe in MS patients but not in healthy subjects may suggest that T cells present in CSF become infected during the disease. This hypothesis is strengthened by the fact that some T cells obtained from CSF of MS patients share characteristics with HTLV-transformed T cells. For example, like HTLV-transformed T cells⁶, one clone from CSF cells of a Swedish MS patient had a low, but significant, number of cells with lobular or multiple nuclei⁸. In addition, most mitogen-induced MS CSF T-cell lines consisted predominantly of OKT3,4-positive cells⁸, as did cells isolated from HTLV-associated T-cell malignancies and cord blood lymphocytes transformed *in vitro* with HTLV-I⁶. Finally, most MS CSF T-cell lines grow to saturation densities of $\geq 2 \times 10^6 \text{ ml}^{-1}$ (ref. 8), like the HTLV-transformed lymphocytes⁶, and grow for extended periods of time in exogenous IL-2 only⁸. The exception is the one clone mentioned above, which is IL-2 receptor-positive but neither produces nor depends

on IL-2 for growth; in this regard, these cells resemble both cord blood and bone marrow-derived lymphocytes transformed by HTLV-I^{30,31}.

If an HTLV-related retrovirus is at all involved in the aetiology of MS, how does one account for three of our findings: (1) the serological detection of anti-HTLV antibodies in less than 70% of the patients; (2) the consistently low level of serum antibody responses in those sera showing some reactivity; and (3) some variation in specificity of the antibody response to HTLV-I, -II or -III? Assuming MS is a disease caused by one agent, the first observation might be explained by the fluctuation in antibody levels during the disease, so that antibodies might not be detected in a single CSF or serum specimen. Alternatively, all MS patients might be infected but only a proportion might respond with the production of antibodies that cross-react with HTLV, or the agent might consistently fail to induce detectable amounts of antibodies. In fact, HTLV-III infection does not induce an antibody response in all infected subjects although the proportion is around 4% (refs 32, 33). Regarding point (2), the low titre of antibodies could be due to transient and/or low-level expression of the putative virus, or to its cross-reactivity with the known HTLV types being very slight. Finally, MS may consist of several subtypes with different aetiologies and the infectious HTLV-related agent may be a factor in only some subtypes. Our data indicate that the agent detected in this study is not HTLV-I, -II or -III. A related but distinct retrovirus might be expected to cross-react weakly with one or more antigenic and genomic determinants of the known HTLVs, just as a weak cross-reactivity with HTLV-I probes led to the discovery of HTLV-II^{34,35}.

The variation in the reactivity of the antibodies with HTLV-I, -II or -III may be explained if the epitopes recognized by these antibodies partially cross-react with the known HTLV types. A novel HTLV related to HTLV-I would be expected to react with HTLV-II antigens in view of the substantial homology between these two retroviruses^{34,35}. Furthermore, some antibodies might be more reactive with HTLV-II proteins than with HTLV-I if the new HTLV had greater homology with HTLV-II than with HTLV-I. However, homology cannot be used to explain the two serum samples from MS patients which were reactive with both HTLV-III and HTLV-I or HTLV-II (Fig. 2, Table 2), as the genome of HTLV-III differs substantially from the other two types. This could conceivably be explained by an HTLV with the properties of a recombinant of the two major types, with variation in expression of specific viral antigen(s) among different patients and even in the course of the disease in a given patient.

The incubation period for HTLV-I and -II is 5–30 yr^{34,36}. A similar incubation period for the putative HTLV-related retrovirus would be consistent with the notion of exposure in early adolescence to any infectious agent that might be involved in the aetiology of MS³⁷.

We have discussed our data as though they indicate the presence and involvement of a novel HTLV-related virus in MS.

If that is the case, our attempts to isolate the virus should eventually be successful. For now, the data are suggestive, but not conclusive.

A blue stellar population in the H I bridge between the two Magellanic Clouds

Radio observations have shown¹ that a common H I cloud surrounds the Magellanic Cloud system. However, no stellar link between the two galaxies has previously been found. The furthest known stellar extension eastward of the Small Magellanic Cloud (SMC) is the blue association of stars found by Kunkel², which lie close to the extreme tip of the 'wing' of the SMC. The SMC wing was discovered by Shapley³, who described it as "a large cloud of faint stars extending eastward from the SMC toward the LMC [Large Magellanic Cloud]". More recently, Westerlund⁴ described the brighter ($V < 20.0$) stellar population of the wing as being a mixture of extreme Population I, OB associations, H II regions and both blue and yellow supergiants. The rest of the Magellanic system shows a strong correlation between H I density and the presence of stellar condensations, and this has led to speculation that stellar associations may be present in the H I extension of the optical wing (the H I bridge indicated in Fig. 1) and also independently in regions of high H I density in the Magellanic stream⁵. Deep H α photography⁶ shows weak diffuse emission between the Magellanic Clouds, supporting the possible existence of an optical counterpart to the H I bridge, but star counts near the eastern tip of the wing⁷ failed to reveal any link and indeed corroborated earlier work on the structure of the wing⁸. We now report the discovery of several hundred blue main-sequence stars in an area reaching 9° east of the SMC, coinciding with the H I ridge extending from the wing. These stars lie midway between the two Clouds and are more than 2 kpc further east than what was believed to be the eastern tip of the SMC wing. The apparent magnitudes of the brightest main-sequence stars suggest an age of ~100 Myr, similar to ages of associations in the wing.

The discovery² of stellar aggregates at the extreme eastern tip of the wing prompted us to investigate a large area to the east of the wing. For this purpose we obtained a pair of UK Schmidt plates (IIIaJ+GG385 and IIIaF+OG590) centred on RA 02 h 37 min, dec. -73° 43'. The plates were scanned and processed by the Automatic Plate Measuring (APM) facility at Cambridge and calibrated from a photoelectric sequence (W.E.K., M.J.I. and S.D., in preparation). Magnitudes (R) and colours ($J-R$) were obtained for over 120,000 stellar objects in a 6°×6° area. This number corresponds to a magnitude limit of $m_J \sim 21$ and $m_R \sim 20$.

The area covered by the plates and its relationship to the Magellanic system are shown in Fig. 1. Three levels of integrated H I column densities are shown for the LMC⁴ and the SMC⁹, corresponding to levels of 4, 8 and $\geq 12 \times 10^{20}$ H I atoms cm⁻². The optical centres¹⁰ of both galaxies are represented by dots.

The colour-magnitude diagram of the 120,000 stars reproduced in Fig. 2 reveals a well-defined blue main sequence, extending upward to $m_R \sim 15$, and well separated from the expected foreground galactic stars. Multicolour photometry¹¹

Fig. 1 The field investigated (square) relative to the Magellanic Clouds represented here by three levels of H I column density: 4, 8 and $\geq 12 \times 10^{20}$ atoms cm⁻². The dots represent the optical centres of the two galaxies.

Fig. 2 A stellar colour-magnitude diagram in photographic J (B_J) and R of the $6^\circ \times 6^\circ$ of sky investigated. A Zero Age Main Sequence (ZAMS) is clearly discernible (dashed line) as are the foreground galactic halo (yellow $J-R \sim 0.8$) and disk (red $J-R \sim 1.9$) stars. Some 4,000 stars are in the region blueward of $J-R=0$.

Fig. 3 The spatial distribution of the stars with colour $J-R < 0$. The tip of the wing (see ref. 8) is outlined (solid line) together with the H I isophote corresponding to 8×10^{20} atoms cm^{-2} (dashed line).

of Cepheids in the system has shown that the colour excess toward the tip of the wing is small, $E(B-V) \leq 0.05$, indicating that these blue stars have magnitudes and colours consistent with a sequence located at roughly the same distance as the Magellanic Clouds. Figure 3 gives the spatial distribution of the $\sim 4,000$ main-sequence stars with $J-R < 0$. These stars represent around 3% of the total stellar population of the 36 deg^2 area. The tip⁸ of the wing and the H I isophotes are outlined. As expected, most of the blue stars, occur in the extreme tip of the wing, seen on the right (Fig. 3). The concentration at RA 02 h 30 min coincides with the previously known stellar aggregate². We see here for the first time a large area of blue stars lying to the north of the extreme tip, and the group of blue stars at RA 02 h 52 min of angular extent $\sim 1^\circ$. This latter group is 9° from the optical centre of the SMC and 12.5° from the LMC, corresponding to distances of 10.6 and 12.5 kpc, respectively, which are well outside the radius¹⁰ of both clouds. Furthermore, Fig. 3 clearly reveals an overall optical counterpart to the H I bridge, although some of the blue stars are apparently in regions of low H I density.

Colour-magnitude diagrams for all the areas possessing a marked excess of blue stars have been analysed separately. Apart from number density of images, all the regions have almost identical blue main sequences (within ± 0.1), confirming that these blue stars indeed belong to the Magellanic Clouds. By statistically removing an equivalent foreground comparison colour-magnitude diagram, it is also possible to search the region with colours $J-R > 0$ for red giants and horizontal branch stars. Preliminary results indicate that the combined number of Magellanic red giants and horizontal branch stars is less than 10% of the number of blue main-sequence stars in the selected areas. Furthermore, for stars with $J-R > 0$, no clumpiness or overall stellar density gradient is discernible across the field, as observed⁷ for the halo region of the SMC. Even limiting the search to those stars having the magnitude and colour of the horizontal branch stars produces no definitive non-uniformity of images. This is not too surprising as these stars form less than 1% of the total population at these magnitudes and colours and are therefore swamped by the foreground component.

As a further check, number density maps of the whole $6^\circ \times 6^\circ$ area were constructed. These reveal a distinct excess of images only in the regions where the extra blue stars are found, confirming that it is the blue main-sequence stars that dominate the bridge population. Also, the noise in the number density map indicates that although the extra stars are visible with hindsight on deep photographs, two-colour photometry is

needed to identify them unambiguously. All this evidence strongly suggests that we are looking outside what is known as the SMC. There is no doubt from the individual colour-magnitude diagrams that the main-sequence stars are at a similar distance to the Magellanic Clouds. Photometry of Cepheids¹² throughout the SMC strongly suggests that the wing is pointing towards us, thus becoming progressively closer as it goes further east. The nearest well-studied¹³ cluster, Lindsay 113, lies in the wing 4.5° east of the optical centre of the SMC at a distance of 58 kpc. This is midway between the accepted distance¹² for the SMC and LMC of 62 and 54 kpc, respectively. We will adopt a preliminary distance of 58 kpc for the Magellanic bridge region, keeping in mind that recent observations¹⁴ have suggested that the distances of both Magellanic Clouds may require a major revision.

At this distance the brightest main-sequence stars are at $V \sim 15$ or $M_V \sim -4$. Adopting an age calibration¹⁵ of the Magellanic Cloud clusters leads to an age estimate of less than 100 Myr for the new blue stellar associations. This is comparable with the ages¹⁶ of clusters and associations in the wing. A study leading to a more accurate knowledge of the chemical composition, age and distance (and hence origin) of the stars in the bridge region is now under way (W.E.K., M.J.I. and S.D., in preparation). Preliminary results from the photographic study indicate that the blue stars in the bridge region have a common origin with similar blue stars in the SMC wing and that they are located midway between the two Clouds.

This study was funded in part by the SERC, UK, and Natural Sciences and Engineering Research Council, Canada. We thank the UKSTU for taking the plates and the members of the APM group for providing the services of the scanning facility. S.D. is on leave from the Université de Montréal.

C₆₀: Buckminsterfullerene

H. W. Kroto*, J. R. Heath, S. C. O'Brien, R. F. Curl & R. E. Smalley

Rice Quantum Institute and Departments of Chemistry and Electrical Engineering, Rice University, Houston, Texas 77251, USA

During experiments aimed at understanding the mechanisms by which long-chain carbon molecules are formed in interstellar space and circumstellar shells¹, graphite has been vaporized by laser irradiation, producing a remarkably stable cluster consisting of 60 carbon atoms. Concerning the question of what kind of 60-carbon atom structure might give rise to a superstable species, we suggest a truncated icosahedron, a polygon with 60 vertices and 32 faces, 12 of which are pentagonal and 20 hexagonal. This object is commonly encountered as the football shown in Fig. 1. The C₆₀ molecule which results when a carbon atom is placed at each vertex of this structure has all valences satisfied by two single bonds and one double bond, has many resonance structures, and appears to be aromatic.

The technique used to produce and detect this unusual molecule involves the vaporization of carbon species from the surface of a solid disk of graphite into a high-density helium flow, using a focused pulsed laser. The vaporization laser was the second harmonic of Q-switched Nd:YAG producing pulse energies of ~30 mJ. The resulting carbon clusters were expanded in a supersonic molecular beam, photoionized using an excimer laser, and detected by time-of-flight mass spectrometry. The vaporization chamber is shown in Fig. 2. In the experiment the pulsed valve was opened first and then the vaporization laser was fired after a precisely controlled delay. Carbon species were vaporized into the helium stream, cooled and partially equilibrated in the expansion, and travelled in the resulting molecular beam to the ionization region. The clusters were ionized by direct one-photon excitation with a carefully synchronized excimer laser pulse. The apparatus has been fully described previously²⁻⁵.

The vaporization of carbon has been studied previously in a very similar apparatus⁶. In that work clusters of up to 190 carbon atoms were observed and it was noted that for clusters of more than 40 atoms, only those containing an even number of atoms were observed. In the mass spectra displayed in ref. 6, the C₆₀ peak is the largest for cluster sizes of >40 atoms, but it is not completely dominant. We have recently re-examined this system and found that under certain clustering conditions the C₆₀ peak can be made about 40 times larger than neighbouring clusters.

Figure 3 shows a series of cluster distributions resulting from variations in the vaporization conditions evolving from a cluster distribution similar to that observed in ref. 3, to one in which C₆₀ is totally dominant. In Fig. 3c, where the firing of the vaporization laser was delayed until most of the He pulse had passed, a roughly gaussian distribution of large, even-numbered clusters with 38–120 atoms resulted. The C₆₀ peak was largest but not dominant. In Fig. 3b, the vaporization laser was fired at the time of maximum helium density; the C₆₀ peak grew into a feature perhaps five times stronger than its neighbours, with the exception of C₇₀. In Fig. 3a, the conditions were similar to those in Fig. 3b but in addition the integrating cup depicted in Fig. 2 was added to increase the time between vaporization and expansion. The resulting cluster distribution is completely dominated by C₆₀, in fact more than 50% of the total large cluster abundance is accounted for by C₆₀; the C₇₀ peak has diminished in relative intensity compared with C₆₀, but remains rather prominent, accounting for ~5% of the large cluster population.

Our rationalization of these results is that in the laser vaporization, fragments are torn from the surface as pieces of the planar

Fig. 1 A football (in the United States, a soccerball) on Texas grass. The C₆₀ molecule featured in this letter is suggested to have the truncated icosahedral structure formed by replacing each vertex on the seams of such a ball by a carbon atom.

graphite fused six-membered ring structure. We believe that the distribution in Fig. 3c is fairly representative of the nascent distribution of larger ring fragments. When these hot ring clusters are left in contact with high-density helium, the clusters equilibrate by two- and three-body collisions towards the most stable species, which appears to be a unique cluster containing 60 atoms.

When one thinks in terms of the many fused-ring isomers with unsatisfied valences at the edges that would naturally arise from a graphite fragmentation, this result seems impossible: there is not much to choose between such isomers in terms of stability. If one tries to shift to a tetrahedral diamond structure, the entire surface of the cluster will be covered with unsatisfied valences. Thus a search was made for some other plausible structure which would satisfy all sp² valences. Only a spheroidal structure appears likely to satisfy this criterion, and thus Buckminster Fuller's studies were consulted (see, for example, ref. 7). An unusually beautiful (and probably unique) choice is the truncated icosahedron depicted in Fig. 1. As mentioned above, all valences are satisfied with this structure, and the molecule appears to be aromatic. The structure has the symmetry of the icosahedral group. The inner and outer surfaces are covered with a sea of π electrons. The diameter of this C₆₀ molecule is ~7 Å, providing an inner cavity which appears to be capable of holding a variety of atoms⁸.

Assuming that our somewhat speculative structure is correct, there are a number of important ramifications arising from the existence of such a species. Because of its stability when formed under the most violent conditions, it may be widely distributed in the Universe. For example, it may be a major constituent of circumstellar shells with high carbon content. It is a feasible constituent of interstellar dust and a possible major site for

Fig. 2 Schematic diagram of the pulsed supersonic nozzle used to generate carbon cluster beams. The integrating cup can be removed at the indicated line. The vaporization laser beam (30–40 mJ at 532 nm in a 5-ns pulse) is focused through the nozzle, striking a graphite disk which is rotated slowly to produce a smooth vaporization surface. The pulsed nozzle passes high-density helium over this vaporization zone. This helium carrier gas provides the thermalizing collisions necessary to cool, react and cluster the species in the vaporized graphite plasma, and the wind necessary to carry the cluster products through the remainder of the nozzle. Free expansion of this cluster-laden gas at the end of the nozzle forms a supersonic beam which is probed 1.3 m downstream with a time-of-flight mass spectrometer.

Fig. 3 Time-of-flight mass spectra of carbon clusters prepared by laser vaporization of graphite and cooled in a supersonic beam. Ionization was effected by direct one-photon excitation with an ArF excimer laser (6.4 eV, 1 mJ cm⁻²). The three spectra shown differ in the extent of helium collisions occurring in the supersonic nozzle. In *c*, the effective helium density over the graphite target was less than 10 torr—the observed cluster distribution here is believed to be due simply to pieces of the graphite sheet ejected in the primary vaporization process. The spectrum in *b* was obtained when roughly 760 torr helium was present over the graphite target at the time of laser vaporization. The enhancement of C₆₀ and C₇₀ is believed to be due to gas-phase reactions at these higher clustering conditions. The spectrum in *a* was obtained by maximizing these cluster thermalization and cluster-cluster reactions in the 'integration cup' shown in Fig. 2. The concentration of cluster species in the especially stable C₆₀ form is the prime experimental observation of this study.

surface-catalysed chemical processes which lead to the formation of interstellar molecules. Even more speculatively, C₆₀ or a derivative might be the carrier of the diffuse interstellar lines⁹.

If a large-scale synthetic route to this C₆₀ species can be found, the chemical and practical value of the substance may prove extremely high. One can readily conceive of C₆₀ derivatives of many kinds—such as C₆₀ transition metal compounds, for example, C₆₀Fe or halogenated species like C₆₀F₆₀ which might be a super-lubricant. We also have evidence that an atom (such as lanthanum⁸ and oxygen¹) can be placed in the interior, producing molecules which may exhibit unusual properties. For example, the chemical shift in the NMR of the central atom should be remarkable because of the ring currents. If stable in macroscopic, condensed phases, this C₆₀ species would provide a topologically novel aromatic nucleus for new branches of organic and inorganic chemistry. Finally, this especially stable and symmetrical carbon structure provides a possible catalyst and/or intermediate to be considered in modelling prebiotic chemistry.

We are disturbed at the number of letters and syllables in the rather fanciful but highly appropriate name we have chosen in the title to refer to this C₆₀ species. For such a unique and centrally important molecular structure, a more concise name would be useful. A number of alternatives come to mind (for

example, ballene, spherene, soccerene, carbosoccer), but we prefer to let this issue of nomenclature be settled by consensus.

We thank Frank Tittel, Y. Liu and Q. Zhang for helpful discussions, encouragement and technical support. This research was supported by the Army Research Office and the Robert A. Welch Foundation, and used a laser and molecular beam apparatus supported by the NSF and the US Department of Energy. H.W.K. acknowledges travel support provided by SERC, UK. High-resolution solid-state NMR of quadrupolar nuclei

Eric Oldfield, Hye Kyung C. Timken,
Ben Montez & R. Ramachandran

School of Chemical Sciences, University of Illinois at
Urbana-Champaign, 505 South Mathews Avenue, Urbana,
Illinois 61801, USA

Quadrupolar nuclei are the most abundant nuclear magnetic resonance (NMR)-receptive nuclei in the Earth's crust, and in many amorphous materials of technological interest (such as zeolite catalysts, ceramics and alloys), and have thus been intensively studied¹⁻⁷. Of particular interest is the ability to resolve and quantitate the various types of sites present in a given material. Here we present a very simple, yet we believe powerful, approach towards the resolution of chemically non-equivalent sites in solids, which combines a conventional high-field spin-echo NMR method with the resolution enhancement of the 'quadrupole shift' approach^{4,7}. We demonstrate its application to the complete resolution of both the (1/2, 3/2) and (3/2, 5/2) transitions of the ²⁷Al nuclei in a mixture of potassium and ammonium alums (KAl(SO₄)₂·12H₂O and NH₄Al(SO₄)₂·12H₂O).

The major problem in spin-echo studies of most quadrupolar nuclei in solids is that a series of echoes is usually obtained^{8,9}. Solomon first reported⁸ the refocusing of first-order quadrupolar interactions using two radio-frequency pulses of the same phase, and Butterworth⁹ was able to differentiate quadrupolar from purely magnetic interactions in various alloys. However, this approach is not particularly useful for minerals and other non-metallic materials, where large magnetic inhomogeneities are absent.

Fortunately, however, Bonera and Galimberti¹⁰ and Weisman and Bennett¹¹ showed that considerable enhancement of the 'desired' 2 τ echo could be achieved by introducing a 90° phase-shift between the two radio-frequency pulses. Moreover, Weisman and Bennett showed (for nuclear spin $I = 5/2$) for the special case of a 90°- τ -45° pulse sequence that the amplitude of the 2 τ echo (central plus quadrupolar contribution) was maximized, while the 'allowed' 3/2 τ plus 3 τ echo amplitude was minimized¹¹. In practice, the 2 τ echo is often the only one observed¹¹, and we show here that the Fourier transform of the echo can yield an essentially undistorted (1/2, -1/2; 1/2, 3/2; 3/2, 5/2) powder spectrum.

Figure 1*a* and *b* show the ²³Na and ²⁷Al spin-echo spectra of NaNO₃ and KAl(SO₄)₂·12H₂O, obtained at magnetic field strengths of 8.45 and 3.52 T, respectively, the response of the potassium alum being obtained in the presence of ¹H dipolar

Fig. 1 Quadrupole-echo NMR spectra of ^{23}Na in NaNO_3 and ^{27}Al in $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, obtained at magnetic field strengths of 8.45 and 3.52 T, respectively. *a*, ^{23}Na spin-echo from NaNO_3 ; *b*, ^{27}Al spin-echo from $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$; *c*, Fourier transform of half-echo in *a* showing central ($1/2, -1/2$) and satellite ($1/2, 3/2$) transitions; *d*, Fourier transform of half-echo in *b* showing central ($1/2, -1/2$) and satellite ($1/2, 3/2$; $3/2, 5/2$) transitions; *e*, de-Paked version of *c* showing the 90° edge, corresponding to $e^2qQ/h \sim 339$ kHz, η assumed ~ 0 ; *f*, de-Paked version of *d* showing the 90° edges of the ($1/2, 3/2$) and ($3/2, 5/2$) transitions, corresponding to $e^2qQ/h \sim 395$ kHz, η assumed ~ 0 .

decoupling (at 150 MHz). No subsidiary echoes were observed for ^{27}Al (and none were expected for ^{23}Na), even though, with our present instrumentation, we were unable to use pulses much stronger than the overall spectral breadth. Nevertheless, Fourier transformation of both responses yielded conventional frequency domain powder-pattern spectra (Fig. 1*c, d*) in which the 90° edges of the $1/2, 3/2$ (Na, Al) and $3/2, 5/2$ (Al) transitions were well resolved.

To provide a more convenient 'high-resolution' presentation, we have applied the 'de-Pakeing' algorithm developed by Bloom *et al.*^{12,13} to the non-integral spin spectra of Fig. 1*c, d*, and show the results in Fig. 1*e* and *f*. For both systems, there were no appreciable second-order effects, and asymmetry parameters $\eta \sim 0$, so narrow-line spectra corresponding to nuclear quadrupole coupling constants, $e^2qQ/h = 339$ kHz (NaNO_3) and 395 kHz ($\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$) were obtained, in good agreement with previous single crystal determinations¹⁴⁻¹⁷.

To illustrate further the usefulness of the method, which can be implemented on a conventional high-field NMR instrument, Fig. 2*a-c* gives the spin-echo, spin-echo Fourier transform powder pattern and de-Paked lineshape for an equimolar mixture of potassium and ammonium alums, again obtained in the presence of ^1H dipolar decoupling. The K^+ and NH_4^+ alum signals have their expected 1:1 intensity ratios. In both cases, the potassium and ammonium alum signals are fully resolved, the outer satellite transitions being slightly more resolved than the inner ones (even though their component linewidths are greater). Further line-narrowing may be possible in other cases by application of homonuclear line-narrowing techniques (when e^2qQ/h values are very small). The quadrupole coupling constants (395 kHz and 441 kHz for potassium alum and ammonium alum, respectively) and asymmetry parameters ($\eta = 0$ for both) show excellent agreement with the single crystal NMR data¹⁵⁻¹⁷, which give $e^2qQ/h = 400$ kHz for potassium alum and 446 kHz for ammonium alum, and $\eta = 0$ for both (since the point symmetry of the ^{27}Al is $\bar{3}$ in both structures).

Fig. 2 Quadrupole-echo NMR spectra of ^{27}Al in a 1:1 molar mixture of $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$ and $\text{NH}_4\text{Al}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$, obtained at a magnetic field strength of 3.52 T, in the presence of ^1H dipolar decoupling. *a*, ^{27}Al spin-echo; *b*, Fourier transform of half-echo showing central ($1/2, -1/2$) and overlapping satellite ($1/2, 3/2$; $3/2, 5/2$) transitions for the K^+ and NH_4^+ alums. *c*, de-Paked version of *b* showing complete resolution of both K^+ and NH_4^+ alums in both satellite transitions, corresponding to $e^2qQ/h \sim 395$, 441 kHz, η assumed ~ 0 .

Overall, we believe that the above results indicate considerable promise for high-field NMR techniques in the differentiation of signals in powder samples from quadrupolar nuclei of identical chemical shifts. The technique should be applicable to systems having larger e^2qQ/h values by using high-power wide-band transmitters at higher field (using smaller sample, low- Q probes). Such an application was limited in the present case by the use of pulses having ~ 0.5 - μs rise and fall times, but should not be limited to systems having long spin-lattice relaxation times. It can be readily implemented (at least for small e^2qQ/h values) on existing conventional Fourier transform NMR instruments, and could thus be extremely useful in the structural analysis of a variety of amorphous solids of interest in the earth, materials and biological sciences. For all nuclei, operation with very wide-bore magnets (to house the very high-voltage capacitors needed for short pulse widths) at the highest magnetic field strengths possible (to minimize second-order quadrupole interactions and 'ringing' effects) will, however, be essential in order to maximize the usefulness of this approach.

We thank M. Bloom and H. C. Jarrell for providing their spectral de-Pakeing programs. This work was supported by the US NSF Solid-State Chemistry Program and by the Biophysics Program, and in part by the US Department of Energy (to H.K.C.T.).

A hydrated aluminophosphate with both 4.8² and 6³ sheets in the 4-connected framework

Joseph J. Pluth & Joseph V. Smith

Department of the Geophysical Sciences, University of Chicago, Chicago, Illinois 60637, USA

Porous aluminosilicates of the zeolite type have become important industrially as ion-exchangers, molecular sieves and catalysts^{1,2}. Topologically, the tetrahedral centres of the oxygen tetrahedra lie at the nodes of various 4-connected three-dimensional nets. Four-connected porous frameworks (AlPO₄) composed of alternating AlO₄ and PO₄ tetrahedra are the basis of a new family of synthetic molecular sieves, which may become important industrially because they lack the strong ion-exchange and catalytic properties of the zeolites³. Aluminophosphates display a wide range of crystal structures because Al can be coordinated to either four, five or six oxygen atoms, some of which may belong to either hydroxyl or water species^{3–12}. As part of a systematic study of the crystal chemistry of aluminophosphates, we have found that the framework of synthetic-phase H3 (ref. 13) (AlPO₄·1.5 H₂O) contains PO₄ tetrahedra alternating between AlO₄ tetrahedra and AlO₄(H₂O)₂ octahedra. As reported here, the 4-connected three-dimensional net formed by linking adjacent Al and P atoms is a new type containing 6.6.6 and 4.8.8. two-dimensional nets joined by up-down linkages. This coexistence of two types of two-dimensional nets in a three-dimensional net suggests that the principle of parsimony should not be adopted too strictly in attempts to invent new nets of potential relevance to molecular sieve technology.

Crystals of a hydrated aluminium phosphate were synthesized by S. T. Wilson, B. M. Lok and E. M. Flanigen of Union Carbide Corporation. The X-ray powder diffraction pattern of the crystals matches that in Fig. 2 of ref. 13. Full details of the X-ray structure determination will be published elsewhere¹². Cell dimensions and atomic coordinates (Table 1) were refined by the least-squares method. Refinement was straightforward except for the H atoms. The positions of H-1 and H-2 were constrained to lie at 0.85 Å from O-9; the same was true for O-10, H-3 and H-4. Whereas these two water oxygens are bonded to Al-2, the last oxygen O-11, is not part of the framework and its position is weakly constrained. Because hydrogen atoms could not be located even from a constrained refinement, it is assumed that O-11 is part of a loosely bonded water molecule.

Figure 1 is a stereo plot showing the positions of all located atoms. Each P atom is tetrahedrally coordinated, and shares an oxygen atom with four adjacent Al atoms. Similarly, each Al-1 atom shares an oxygen atom with one P-2 and three P-1 atoms. Each Al-2 atom, however, is bonded to two water molecules as well as four framework oxygens. Such an octahedral complex, AlO₄(H₂O)₂, is also found in metavariscite⁵. The atomic positions in Table 1 correspond to AlPO₄·1.5 H₂O instead of the AlPO₄·1.67 H₂O listed by d'Yvoire¹³. The complex dehydration and rehydration properties of H₃ could be interpreted in terms of easy loss of the water molecule at position O-11, conversion of the octahedral complex AlO₄(OH)₂ to a tetrahedral complex AlO₄ by loss of two water molecules at a higher temperature, and adsorption of water by the dehydration product on cooling in a humid atmosphere; however, further structure determinations are needed to clarify this.

Fig. 1 Stereo plot of H3 structure type, projected down the *a* axis with *c* pointing upwards and *b* sideways. Small open and solid circles at line intersections represent Al and P atoms, respectively. Large open circles represent oxygen atoms. Pairs of H atoms (small dots) are shown for each water molecule attached to an Al atom, but not for the loosely bonded water molecule.

When the water molecules are ignored, the structure can be regarded as a 4-connected tetrahedral framework which can be compared with the growing list of theoretical and three-dimensional nets (ref. 14 and refs therein; also refs 15, 16). The H3 net is novel, and it is interesting because it is based on up-down linkages between both 6³ and 4.8² nets. A portion of a 3-connected 6.6.6 two-dimensional net is shown in plan view in Fig. 2A; each node is connected by three edges, each of which is part of a circuit of six edges. The continuous lines of Fig. 2B represent part of a 3-connected 4.8.8 two-dimensional net. An infinite number of three-dimensional nets can be obtained by stacking horizontal 6.6.6 two-dimensional nets in a vertical pile and connecting adjacent nodes by a vertical linkage¹⁷. Because only one linkage can be added to each 3-connected node, there are two choices for each node. The simplest three-dimensional nets have been enumerated, and some are found in crystalline materials¹⁷. Similar enumeration has been done for 4.8.8 nets connected by up-down linkages¹⁸. The H3 tetrahedral framework is shown in clinographic perspective in Fig. 2C. A 6.6.6 net (centre) is connected to 4.8.8 nets above and below it by vertical linkages (dashed lines). Each 3-connected node marked by an open circle is joined to a node above it (solid circle) so that each node becomes 4-connected. Regular alternation of 6.6.6 and 4.8.8 nets in the vertical stack generates an infinite 4-connected three-dimensional 3D net. The 6.6.6 and

a = 19.352(1), *b* = 0.727(1), *c* = 9.762(1) Å; orthorhombic, Pbcn. Room temperature. CuK α . Crystal 40 \times 40 \times 220 μ m, elongated *c*. 1,439 unique diffraction intensities. Anisotropic thermal parameters. *R* = 0.04. $U_{iso}(\times 10^3)$ is given for hydrogen atoms, and $U_{eq}[(10^3/3)\sum_i U_{ij}a_i^*a_j^*(a_i, a_j)]$ is given for the other atoms. Number in parentheses represent standard error.

Fig. 2 Topological drawings. **A**, Plan view of a portion of a 6.6.6 3-connected two-dimensional net. **B**, Plan view of a portion of a 4.8.8 3-connected two-dimensional net (continuous lines). The corner marks outline the *c*-axis projection of the unit cell for the H3 structure type idealized to the regular geometry for up and down linkages from a 4.8.8 two-dimensional net (up, node marked by solid circle; down, unmarked node). Dotted and broken lines show, respectively, side views of the 4.8.8 and 6.6.6 nets in *C*. **C**, Perspective drawing of the up-down linkages (dashed lines) between alternating 4.8.8 and 6.6.6 two-dimensional nets. Twelve 4-rings and one 6-ring are stippled to strengthen the perspective.

4.8.8 nets are distorted from the ideal shapes when the linkages are vertical. In the H3 structure (Fig. 1), the nets are considerably crinkled to allow for bonding to the water molecules, but may become more regular on complete dehydration.

The H3 structure can also be described in terms of up-down linkages between a vertical stack of 4.8.8 nets. Figure 2B shows a plan view of a three-dimensional net obtained when adjacent groups of four linkages (solid circles) alternate with four downward linkages (unmarked nodes). The unit cell for the most regular geometry and an edge length of 3.1 Å is orthorhombic, with $a = 17$ Å, $b = 10$ Å, $c = 8.5$ Å, space group Abmm, 32 nodes (Z_c) per cell, 16 nodes (Z_i) in the asymmetric unit, circuit symbol $4^3 6^2 8$. (Z_c is the number of atoms in the crystallographic unit cell and Z_i is the number of atoms in the smallest unit cell.) This net was not enumerated previously¹⁸ because its a repeat of 17 Å is longer than the upper limit of 15 Å selected by Smith and Rinaldi¹⁹; it is now denoted as net 24a. Crinkling of the framework in the H3 structure changes the above cell to $a = 19.35$ Å, $b = 9.73$ Å, $c = 9.76$ Å, Pbc_a; in particular, the double-crankshaft chain along the *c* axis is stretched out considerably over that in the feldspar structure. It should be emphasized that there are two 4.8.8 two-dimensional nets in the H3 framework; one is seen in plan view in Fig. 2B, and the other in side view (dotted lines). The 6.6.6 net is also shown in side view (dashed lines).

The complex bonding properties of the Al and P atoms in the H3 structure, and in particular the existence of alternating 6.6.6 and 4.8.8 two-dimensional nets, suggests that the principle of parsimony should not be taken too strictly in attempts to invent new nets and crystalline materials of potential use in molecular sieve technology. Furthermore, the geometrical flexibility of the two-dimensional component nets of three-dimensional nets (for example, 6^3 net; ref. 20) must be considered in attempts to invent new types of linkages in three-dimensional nets.

We thank E. M. Flanigen, L. Patton and S. T. Wilson for reviewing the manuscript, the NSF for grant CHE 84-05167, Union Carbide Corporation (Linde Molecular Sieves) for financial support, and three referees for comments which led to replacement of an incomprehensible projection by a perspective drawing.

Meteoritic evidence that graphite is rare in the interstellar medium

Joseph A. Nuth

Solar System Exploration Division, Office of Space Science and Applications, NASA Headquarters, Washington, DC 20546, USA

This letter discusses the carbonaceous material from several distinct astrophysical environments that has been identified in primitive meteorites. Most of this material is not well-crystallized graphite, but ranges from kerogen-like macromolecular organic matter to poorly graphitized carbon. Of the small fraction of the carbonaceous material which is graphite, most of this may have resulted from the graphitization of macromolecular precursors in the solar nebula. Since graphite is more stable than those precursors, pre-existing interstellar graphite should have survived in meteorites to at least the same extent as did other forms of carbon. I conclude from this dearth of graphite that graphitic carbon was not a major component of the interstellar dust at the time of the formation of the Solar System.

Several forms of carbon are present in the primitive meteorites¹. Some of this carbon may have been produced in the primitive solar nebula¹, some by ion-molecule reactions in interstellar space^{2,3} and a small fraction could have been formed in the expanding shells of red giants⁴, novae⁵ and supernovae⁶. The bulk of meteoritic carbon is 'ordinary' in the sense that it is neither the carrier of an isotopically distinct rare gas component nor itself distinguishable by an 'anomalous' $^{13}\text{C}/^{12}\text{C}$ ratio or associated anomalous $^{15}\text{N}/^{14}\text{N}$ or D/H ratios. The 'exotic' component of primitive meteorites is important not only because of its potential to record subtle clues about the nucleosynthetic process⁷, but also as evidence that some interstellar materials survived the formation of the Solar System and were incorporated relatively intact into meteorites, a possibility suggested by Cameron⁸ as early as 1973.

Anomalous material is that in which the isotopic ratio of an element differs from the standard 'cosmic' isotopic ratio. Both refractory and volatile elements have been shown to be isotopi-

cally anomalous (reviewed in ref. 7). Anomalies in volatile elements are most relevant in the present context because their preservation indicates that some delicate features of pre-solar interstellar grains can still be found in primitive meteorites. Numerous isotopically anomalous rare gas components are known to exist in the meteorites and several of these are thought to pre-date the collapse of the solar nebula. A ^{22}Ne -rich gas component is released from C1 and C2 chondrites at temperatures of 1,075–1,375 K (ref. 9). Recent work¹⁰ has shown that pure ^{22}Ne can be released from a carbonaceous carrier phase at temperatures as low as 875 K. It is now thought that this neon results from the decay of ^{22}Na which condensed on grains formed in the ejecta of a nova. A mixture of xenon isotopes, designated xenon HL, is released from carbonaceous chondrites at temperatures of 875–1,375 K (ref. 11). Xenon HL is enriched in the xenon isotopes 124, 126, 134 and 136 and is thought to have formed in the outflow around a supernova. Another mixture of xenon isotopes, released at 1,375–1,875 K, is enriched in the xenon isotopes 128, 130 and 132 (ref. 4). The composition of this component matches the predicted ratio of xenon isotopes produced via the s-process in red giant stars¹².

It is impossible to overstate the potential influence of secondary metamorphic processes which may have altered the structure or composition of interstellar grains that had survived the 'nebular' phase of Solar System formation. These processes are undoubtedly the source of the abundant graphite found in iron meteorites¹³ and it has been suggested that similar processes may be the source of all meteoritic graphite, even that found in chondrites¹⁴. The existence of the anomalies discussed above, however, indicates that it is possible for some pre-solar grains to have survived relatively intact to the present time. The observed release temperatures indicate that many surviving pre-solar materials were never exposed to temperatures above 1,000 K. Such conditions should not be unfavourable enough to destroy pre-existing interstellar graphite grains and, as noted previously, it has been suggested that the graphite observed in chondrites may have formed in this environment¹⁴.

Most accepted models of interstellar grains consist of various mixtures of graphite, 'silicate' and additional minor components^{15,16}. Graphite is included in these models not only because it can explain the observed peak in the interstellar extinction curve at 220 nm, given certain specific conditions, but also because it is the most stable form of solid carbon in interstellar conditions. (It has the additional advantage that a well-determined set of optical constants is available from the literature.) Millar and Duley¹⁷ have suggested that the 220-nm 'bump' is produced by crystalline magnesium oxide grains, while Hoyle and co-workers¹⁸ have suggested that the observed extinction feature might be caused by various organic materials found in biological systems. More recently, Sakata *et al.*¹⁹ have shown that a 'quenched carbonaceous composite' (QCC), which is a solid soot-like residue produced in a methane plasma discharge, might yield an acceptable fit to the 220-nm extinction peak. Finally, ultraviolet observations by Hecht *et al.*²⁰ have shown that the extinction properties of the dust produced around R Corona Borealis stars are consistent with the properties of amorphous or glassy carbon²¹, rather than with those of graphite. This is especially significant as R Corona Borealis stars are both carbon-rich and hydrogen-deficient ($\text{C}/\text{H} > 100$ in some cases). In such conditions, hydrocarbon formation should be greatly suppressed and there would be relatively few kinetic inhibitions to the formation of graphite²². Failure to form graphite particles in such favourable conditions seems to lessen the probability of their formation in the more common, hydrogen-rich stars that are the source of most interstellar grains²³.

True 'interstellar' carbon has been detected in meteorites² and is distinguished by a greatly enhanced D/H ratio, thought to have been produced through ion-molecule reactions in very cold interstellar clouds²⁴. Such material is not graphite, but consists of a macromolecular kerogen-like polymer¹, a typical composition for which is 76.5% C, 4.5% H, 2.4% N, 4.3% S and 12.3% O (by difference) on a dry, ash-free basis²⁵. Rietmeijer

and Mackinnon¹⁴ have suggested such macromolecular carbon as a possible source material that was metamorphosed to produce the graphite observed in the chondrites.

The facts may be summarized as follows. Graphite is more stable than either the poorly graphitized carbon or macromolecular, kerogen-like organic material observed in meteorites, and therefore should have survived to at least the same degree as did these other forms of carbon. Macromolecular interstellar carbon is found in carbonaceous chondrites, as are the somewhat more fragile 'grains' which contain trapped noble gas components indicative of their formation in various circumstellar environments. Graphite is not observed in the primitive meteorites except in trace amounts quite easily accounted for by the metamorphism of less stable carbonaceous precursors. Such metamorphic processes should not have destroyed pre-existing graphite grains. It therefore seems logical to conclude that graphitic carbon was not a major component of interstellar dust at the time the Solar System formed. Since graphite is not observed to form in R Corona Borealis stars, a circumstellar environment which should be more favourable for the production of graphite grains than a typical carbon-rich circumstellar outflow, we can also infer that newly formed carbon particles are not graphitic. For this reason we might be justified in concluding that graphite is likely to be only a minor component of the modern interstellar dust population. This conclusion may be consistent with a recent suggestion by Hecht²⁶ that the 220-nm bump arises from a population of extremely small graphite grains which would constitute only a small fraction of the total mass of the solid carbonaceous component of interstellar dust.

Most of the questions following from these rather straightforward interpretations can only be answered by detailed laboratory measurements of the appropriate materials and processes. For example, the optical properties of the macromolecular organic component of the meteorites and of QCCs need to be measured as a function of 'metamorphic grade' in order to determine the strength, width and stability of any potentially observable spectral features. Similarly, the effects of the space environment on such materials should be investigated; for example, the effects of irradiation by cosmic rays, X rays or ultraviolet light, the degree of reprocessing induced by shocks and the degree to which thermal annealing can cause 'graphitization'. In addition, it may be possible to use meteoritic data, such as measurements of the abundances of specific 'stellar' isotopic signatures, to place an upper limit on the efficiency with which grains are destroyed in the interstellar medium. Clearly the science of meteoritics can offer considerable data to astrophysicists. Closer cooperation and more communication between these communities is needed to ensure that the available data are used to their fullest potential.

This work was performed while I held a NASA NAS/NRC Research Management Associateship in the Solar System Exploration Division at NASA Headquarters. I acknowledge the helpful advice and suggestions of Bert Donn, Frans Rietmeijer and John Kerridge.

Formation of mesosiderites by low-velocity impacts as a natural consequence of planet formation

John T. Wasson*† & Alan E. Rubin*

* Institute of Geophysics and Planetary Physics and † Departments of Earth and Space Sciences and of Chemistry and Biochemistry, University of California, Los Angeles, California 90024, USA

Mesosiderites are an enigmatic class of stony-iron meteorites composed of roughly equal amounts of pyroxenitic and basaltic silicates and metallic iron-nickel; olivine is rare. We suggest here that, during the period of planet formation, mesosiderites originated by the low-velocity collisions of large metallic core fragments with the surface of a differentiated asteroid-size body. Relative velocities of the asteroids native to this region were low ($\leq 1 \text{ km s}^{-1}$) because it was distant from massive protoplanets. However, a few differentiated asteroids were destroyed by high-velocity collisions with interlopers perturbed by protoplanets into highly eccentric orbits. These collisions reduced mantles and crusts to small silicate fragments but left cores in the form of large, durable metal fragments. Mesosiderite-like pyroxenite-basalt-metal mixtures were formed when large core fragments accreted at low velocities to the regolith of an intact asteroid; the metal contents of other regolithic regions remained low. Most of the olivine in mesosiderite and howardite breccias we attribute to the mantles of the disrupted parent bodies. The low ($12\text{--}20 \text{ mg g}^{-1}$) olivine contents indicate that the amount of debris accreted from disrupted asteroids was small relative to the volumes of the regoliths.

Because differentiated bodies with basalt-rich crusts are expected to have ultramafic mantles and metal-rich cores, models in which mesosiderite basalt and metal are proposed to have originated in the same body cannot easily explain the scarcity of olivine in these stony-iron meteorites. For example, one recent suggestion is that basaltic crustal blocks foundered and sank through a molten peridotite mantle and were then invaded by molten metal from the core¹. This model requires an implausible thermal history to explain the survival of basalt (melting temperature $\sim 1,400 \text{ K}$) exposed to molten mantle and core material ($T \geq 1,800 \text{ K}$).

The least recrystallized mesosiderites (Fig. 1a) are impact breccias, consisting of poorly sorted, angular, igneous silicate clasts, recrystallized breccia clasts and metal nodules in a matrix of metallic Fe-Ni and silicate grains²⁻⁵. The mesosiderites that have undergone the greatest thermal processing are clast-laden impact melt-rocks in which immiscible silicate and metal-sulphide liquids coexisted^{5,6}. Evidence for brief high-temperature events, inferred from mineralogical disequilibrium⁷, also support the proposal that mesosiderites are impact products.

The model invoking core accretion to basalt-rich regolith⁸ has not gained acceptance because relative impact velocities in the asteroid belt ($\sim 5 \text{ km s}^{-1}$) are too high to allow a projectile/target mass ratio near unity. Although previous workers⁹ recognized that low ratios would be expected at lower relative velocities ($\leq 1 \text{ km s}^{-1}$), no scenario leading to such low velocities has been proposed.

The differentiation of planetary bodies normally results in the extrusion of basaltic lavas. Pyroxenitic cumulates could lie immediately below these basalts. Spectral evidence of basalt on the asteroid 4 Vesta^{10,11} suggests that many asteroid-size bodies that formed within Vesta's orbit (2.4 AU from the Sun) were differentiated because most plausible asteroidal heat sources

Fig. 1 a, Photograph of the Mt Padbury subgroup 1A mesosiderite (Smithsonian Institution specimen USNM 3454) showing angular silicate clasts, metal-rich breccia clasts and metal-sulphide nodules within a metal-silicate matrix. Metal grains have been finely comminuted and intimately mixed with silicates through a series of impacts. b, Photograph of the Estherville subgroup 3/4 A mesosiderite (Smithsonian Institution specimen USNM 1025) showing many large rounded metal nodules within a silicate matrix. Estherville suffered less extensive impact reworking than many other mesosiderites.

increase in efficiency with increasing proximity to the Sun. This is obvious for Sun-centred sources such as solar wind-induced electrical currents, but is also true for impact heating, because relative velocities are larger nearer the Sun. Heating of planetesimals by ^{26}Al is more efficient for objects forming earlier in the history of the Solar System; a simple model proposed by Safronov¹² suggests that planetesimals formed earlier nearer the Sun. Internal isochrons determined for eucrites and howardites¹³⁻¹⁶ show that the melting of these bodies occurred within 50 Myr of the formation of chondrites.

The oxygen-isotope compositions of the possibly martian SNC meteorites are only 0.4% $\delta^{17}\text{O}$ above the terrestrial fractionation line¹⁷, supporting the suggestion that primitive bodies that formed in the inner Solar System had O-isotope compositions near this line¹⁸. The O-isotope compositions of mesosiderites and related differentiated meteorites (eucrites, howardites and diogenites) lie equally near the terrestrial fractionation line¹⁹, suggesting that these meteorites also formed in the inner Solar System, perhaps inside 1.5 AU.

Wasson and Warren²⁰ cited evidence in support of the idea that the Moon formed by the circumterrestrial accretion of silicate fragments from differentiated asteroid-size bodies. It seems plausible that, at that time, more than 90% of the bodies in heliocentric orbits having radii near 1 AU were differentiated. We suggest that a similar fraction was differentiated at the mesosiderite formation location. Eucrites, howardites and mesosiderites are unlikely to be from Vesta²¹, because this asteroid is only one of a very large set of differentiated bodies. Fragmented members of this set are far more plausible parents.

According to the scenarios for planet formation proposed by Safronov¹² and Wetherill²², about 100 Myr was required between the stage of planetesimal formation by gravitational collapse to the growth of the inner planets to 95% of their present sizes.

At some epoch during planet formation, most bodies were in low-inclination, nearly circular orbits and average relative velocities in the inner Solar System were $\sim 1 \text{ km s}^{-1}$. Such low velocities would be preserved until 10^{26} -g, Mars-size bodies in eccentric orbits passed through the region. If some distant proto-planets were already Mars-size, some asteroid-size bodies in their vicinities could have been perturbed into eccentric orbits that caused them to pass through the mesosiderite formation region with relative velocities of $5\text{--}10 \text{ km s}^{-1}$. Impacts with these high-velocity interlopers fragmented a few differentiated native bodies into crust, mantle and core debris, the relative masses of these materials probably being about 10%, 65% and 25%, respectively. In those cases in which the high-velocity interloper was much smaller than the body it destroyed, the fragments of both bodies ended up in heliocentric orbits that were nearly circular. Weak crusts and mantles broke into small pieces; the more durable metal cores remained largely intact.

The accretion of a metallic projectile onto a basalt-rich regolith at a velocity of $\sim 1 \text{ km s}^{-1}$ should form large amounts of materials in which the metal/silicate ratio is approximately unity. Some blocks of metal or silicate would not be reduced to the millimetre size typical of mesosiderites, but those with dimensions $\geq 20 \text{ cm}$ might not be recognized as mesosiderites if they fell to Earth as individual meteorites. The textures of some mesosiderites attest to several generations of breccia formation (Fig. 1a); thus, a series of impacts may have reduced the mean grain sizes to those observed. Estherville (Fig. 1b) contains large (1–3 cm diameter) metal nodules and has probably experienced less extensive impact reworking than mesosiderites possessing fine-grained intimate mixtures of metal and silicate (for example, Mt Padbury, Emery, Mincy). Continuing impacts may have generated sufficient heat to cause metamorphism or even incipient melting in some mesosiderites.

Because, in a typical asteroid, the mass of the peridotitic mantle is expected to be about three times greater than the mass of metal in the core, we expect the proportion of accreted olivine to be more abundant than that of metal in the regolith. If olivine was mainly accreted as small debris, the amount of olivine in mesosiderites can be used as a measure of the fraction of the regolith composed of material derived from the accretion of one or more disrupted differentiated bodies. The median olivine content of mesosiderite silicates ($\sim 16 \text{ mg g}^{-1}$)²³ implies that $\sim 25 \text{ mg g}^{-1}$ of the regolith accreted from this source. The howardite regolith breccias provide a test of this scenario; they have chemical and O-isotope compositions nearly indistinguishable from those of the silicate portions of the mesosiderites, and probably formed either on the mesosiderite body or on a neighbouring body. Their median olivine content ($\sim 12 \text{ mg g}^{-1}$; ref. 24) is similar to that of mesosiderites.

Large ($\sim 1 \text{ cm}$) olivine clasts in Mt Padbury, Mincy, Pinnaroo, Vaca Muerta, and West Point have compositions ranging from Fa_{8-12} (refs 2, 25–27); in Emery such clasts range from Fa_{18-28} (ref. 26). The compositional range of the large clasts is narrower than that of all mesosiderite olivine clasts (Fa_{9-42})²⁸ and is similar to that (Fa_{10-30}) calculated for the lunar mantle from magma ocean models²⁹. These observations are consistent with a mantle origin for mesosiderite olivine. Olivine composition is best preserved in large clasts; fine-grained olivine tended to become more ferroan as a result of equilibration with the much more abundant indigenous mafic silicates in the regolith.

If a negligible ($<10\%$) fraction of mesosiderite olivine is indigenous, the observed 16 mg g^{-1} of mantle olivine implies that $\sim 5 \text{ mg g}^{-1}$ of the regolith consisted of core materials. This low abundance is not inconsistent with the fact that metal accounts for $\sim 500 \text{ mg g}^{-1}$ of mesosiderites if we assume that the metal from disrupted asteroids primarily resided in large ($>100 \text{ m}$) fragments. Mesosiderites formed where these objects accreted, whereas metal contents of other regolithic regions remained low, as in howardites. Because the metal content of the mesosiderites is 100 times greater than that estimated for the entire regolith, mesosideritic regolith is inferred to have formed only 1% of the parent body surface.

There are two compositional subgroups (A and B) of mesosiderites, possessing different modal abundances of orthopyroxene, plagioclase and tridymite^{5,23,30}. The somewhat different mean Ir/Ni ratios ($\times 10^5$) of the metal in these groups (3.6 ± 0.91 and 5.1 ± 1.2 , respectively)⁸ suggest that metal core fragments accreted to at least two distinct regolithic regions.

Mesosiderite metal compositions are roughly chondritic^{8,31}. Most cores seem to have formed by fractional crystallization³², but most core fragments are approximately chondritic. The Rayleigh equation can be used to show that nearly half the volume of a metal core would have siderophile ratios within a factor of 3 of the chondritic ratio. This is the case even for elements having extreme solid-liquid distribution coefficients (k) such as Au ($k=0.4$) and Ir ($k=3$).

The moderately high abundance for mesosiderites among meteorite falls can be accounted for by biases resulting from parent body ejection, space erosion and the rigors of atmospheric passage, all of which favour the tough, metal-rich mesosiderites over the more friable howardites.

The only mesosiderite property seemingly incompatible with a near-surface origin is the apparently slow cooling rate below $\sim 800 \text{ K}$ inferred from metallographic evidence. Powell³ and Hewins³³ estimated this rate to be $\leq 1 \text{ K Myr}^{-1}$. Nevertheless, it is possible that it was not monotonic cooling, but low-temperature ($600\text{--}700 \text{ K}$) annealing or thermal cycling for long time periods that produced the metallographic structures. Even if slow cooling actually occurred, the burial depth^{34,35} could be as low as $\sim 15 \text{ km}$ if the thermal diffusivity was similar to that of the lunar regolith ($10^{-4} \text{ cm}^2 \text{ s}^{-1}$)³⁶. Such a regolith depth is plausible for a body accreting material at low relative velocities.

Thus, it seems probable that mesosiderites formed when asteroid-size bodies were still growing. We suggest that many such bodies in the inner Solar System differentiated before accumulation was complete. If a few of these differentiated bodies were disrupted by high-velocity interlopers, it is inevitable that some of their fragments would accrete at low velocities to the basalt-rich regoliths of bodies that avoided disruption. Olivine contents reflect the fraction of the regolith from this source. Mesosiderite-like materials were produced in those rare regolith locations where large core fragments accumulated. Selection biases enhanced the flux of mesosiderite-like breccias relative to that of howardite-like breccias onto the Earth's surface.

We thank G. W. Wetherill, R. H. Hewins and J. S. Delaney for useful comments on earlier versions of this manuscript and T. B. Thomas for the photographs of Mt Padbury and Estherville. This work was supported by NASA grant NAG 9-40.

A large-scale meridional circulation in the convective zone

E. Ribes, P. Mein & A. Mangeney

Observatoire de Paris, Section d'astrophysique de Meudon, 92190—Meudon, France

Many attempts have been made to detect, at the solar photospheric level, large-scale motions related to the Sun's global convection and dynamo (see ref. 1). Because these motions are likely to be influenced by solar rotation, one might expect that they would take the form of 'bananas' aligned with the solar rotation axis², as a result of the Taylor-Proudman constraint. The Paris observatory has one of the longest series of spectroheliograms, dating back to 1919. In view of the current interest in the history of solar activity, we have started to digitize the collection³. This allows us to measure rotational rate and meridional drift for individual sunspots with an accuracy of a few ms^{-1} for the best seeing conditions at Meudon. A new phenomenon, which may lead us drastically to revise our ideas on the large-scale convection of the Sun, can immediately be seen. Newly-born sunspots trace a roughly axisymmetric meridional circulation, in the form of four zonal bands, with relatively large velocity amplitude. If these drifts are assumed to trace fluid motions at some level in the solar envelope, the resulting circulation pattern cannot be associated with the 'banana' cells mentioned above. We report here results based on two sets of data; one involves a detailed analysis of two periods, each covering five solar rotations while the other is essentially qualitative and results from eye-estimates of the spot meridional drifts over much longer time sequences.

The first period (Carrington rotations 1547 to 1551) spans sunspots at the maximum of the solar cycle 20th, the second (Carrington rotations 1587 to 1591) corresponds to the declining phase. Twenty new bipolar groups were born on the visible disk for each period. A third sequence covering the summer of 1967 (ascending phase) has been partially analysed and confirms the following results.

A meridional circulation pattern can be seen in Fig. 1. This is due to young sunspots, and it is larger than in any possible experimental error. It consists of four latitude bands, two in each hemisphere, each pair with opposite directions of circulation. Furthermore, the sense of the meridional drift within each band reverses during the solar cycle. For example, in 1969, sunspots born between latitudes 10° and -21° move towards the equator while sunspots born beyond these latitudes move towards the poles. In 1972, sunspots born within $14^\circ 5'$ and -17° move towards the poles while outside this range, they move towards the equator. Meridional velocities range from zero to 100 m s^{-1} (1° day^{-1} corresponds to 130 m s^{-1}). This value is compatible with convective velocities predicted for giant cells⁴.

One property of the meridional circulation is that it is roughly axisymmetric. Although sunspots are often found at certain preferred longitudes, our data sample a fairly wide range of longitude, especially in the declining phase of the cycle; the observed drifts do not seem to depend on longitude. However, this property of axisymmetry should be confirmed over a larger statistical sample.

Fig. 1 The meridional circulation traced by young sunspots plotted as a function of latitude for the 1969 and 1972 sequences. \times , Leading sunspots; \bullet , following sunspots. In the northern hemisphere, a positive meridional drift ($\Delta B > 0$) indicates that spots are moving towards the north pole, while a negative drift ($\Delta B < 0$) corresponds to a displacement of spots towards the equator.

The rotational rate of young spots is nearly constant with latitude. The synodic leader's rate ($14^\circ 22'$ per day in 1969) is larger than the follower's, as expected from the rise of the magnetic loop (the difference is about $1^\circ 5'$ for the first day and drops rapidly during the next days). The mean deviation, σ , of $0^\circ 7'$ for the leaders and $0^\circ 5'$ for the followers is mainly due to some low latitude spots (at the boundary of the two latitude bands) and does not reflect the differential rotation. Note that the large σ value is partly due to the difficulty of observing young spots on the first day of their emergence. The rotation rate, Ω , at the depth where the spots are anchored should be determined from the centre of gravity of the emerging magnetic loop. But because this is unknown, we used the midpoint between the leaders and the followers. Ω is then approximately equal to the surface equatorial rate. This result is consistent with the deep solid rotation implied by the observed rotational splitting of global oscillations^{5,6}. It also indicates that young spots are better tracers of the deep convective layers than older spots which exhibit a pronounced differential rotation^{7,8}.

The average rotational rate increases by 5% between 1969 and 1972, an increase comparable with the σ value of young spot rotation. This effect is in qualitative agreement with the report⁹ that the solar rotation is faster at the minimum of the cycle. Our sample is too small to allow a quantitative comparison to be made, however.

The question then arises, of whether this meridional circulation of the young spots traces fluid motions at some level in the solar envelope. There are several arguments which suggest that it does.

First, sunspots usually emerge at the surface as simple dipolar magnetic features. When the magnetic loop rises, the leading and the following spots diverge and, a few days later, the following spot starts to fragment and gradually disperses into the general surrounding magnetic field, leaving only the leading spot as an identifiable feature. If one accepts that sunspots are anchored deeply in the convective zone¹⁰, then the drag exerted by the surrounding plasma on the magnetic tubes should be much stronger when the magnetic structure is more complex, that is in the later stage of the spot's life. Thus, newly-born spots are probably the best tracers of fluid motions in the deep convection zone where the dynamo process is supposedly acting.

Second, the spot circulation seems to be related to the large-scale, long-lived, magnetic structures outlined by the $H\alpha$ filaments. The procedure used to look at these structures is

Fig. 2 Evidence of azimuthal rolls (dashed arrows) from the observed meridional circulation of young sunspots (solid arrows) and the drift of long-lived $H\alpha$ filament trajectories (solid lines). The direction of rotation seems to be associated with the magnetic polarity. A new roll appears every 2 or 3 yr. Sunspot activity seems to be concentrated near the updrafts (u) more than near the downdrafts (d).

Fig. 3 Contour maps of differences from average differential rotation (intervals are ± 32 , ± 16 , ± 8 and $\pm 4 \text{ m s}^{-1}$) obtained by Snodgrass and Howard¹². Dashed lines and solid lines correspond to smaller and larger rotational shear. The azimuthal rolls (thin lines) seem to influence the angular momentum transport by reducing the rotational shear. The direction of rotation of the azimuthal rolls is indicated by the dashed arrows.

similar to that used by Makarov¹¹. A mean latitude is assigned to every filament band present on the solar surface during one rotation. A three-rotation-average for each band is then taken. The filaments bands drift with time. If we accept MacIntosh's claim that $H\alpha$ filaments outline the boundaries of regions of unipolar magnetic fields, we can determine an azimuthally-averaged magnetic pattern of alternating polarity. We have disregarded short-lived $H\alpha$ filaments which introduce noise in the data (in contrast with Makarov). As shown in Fig. 2 (see also ref. 11), the magnetic pattern is not random and consists of large-scale azimuthal magnetic regions. Moreover, the magnetic pattern drawn by $H\alpha$ filaments (solid lines in Fig. 2) fits the critical latitudes of the zonal meridional circulation. It is difficult to see how such a pattern could be established other than by large-scale motions. The remarkable coincidence between the circulation pattern and the magnetic pattern suggests that we are looking at azimuthal rolls.

Third, the circulation pattern reflected by young spots interacts with the transport of angular momentum. Snodgrass and Howard¹² have noticed periodic changes in the differential rotation close to sunspot maximum. By superimposing the azimuthal pattern on their data (Fig. 3), it can be seen that the presence of rolls is restricted to the latitudes which have less rotational shear. This is a natural consequence of a meridional circulation in the form of several counter rotating cells.

From these converging arguments, a new picture of the dynamics of the convective zone and the dynamo action emerges. Four to six azimuthal rolls are present, having widths of $\sim 20^\circ$ – 40° with a lifetime of several years. The direction of rotation of a roll is associated with its magnetic polarity. Every 2 or 3 yr, a roll dislocates and a new one appears. The appearance of rolls and their dislocations seems to be related to sunspot activity. In particular, new spots are found mostly in the vicinity of the boundaries between two adjacent rolls. They arise preferentially where the two rolls are diverging rather than converging. This suggests that magnetic fields are expelled by upward motions¹³. After each bifurcation of a roll (in 1967, 1969, 1970 and 1971), a new one appears and the updraft situation moves closer to

the equator. This could explain the shift in latitude observed in the so-called Maunder butterfly diagram of sunspots.

Is there any connection with the giant convective cells which have been invoked³ but never detected? It is hard to give a definitive answer as our method of analysis is biased towards larger-scale motions and precludes the detection of smaller-scale motions such as the giant cells mentioned previously. However, the velocities we have observed are comparable in magnitude to convective velocities calculated for the deep convection zone⁴. This is a very strong argument in favour of a convective origin for the meridional circulation of young spots. If this is the case, we must relax the Proudman–Taylor's constraint. The radial rotational shear, inferred from helioseismology⁶, is too weak in the convective zone to be relevant. On the other hand, a toroidal magnetic field of 10^3 G could force the large-scale convection to take the form of rolls aligned with the azimuthal direction¹⁴.

We thank Drs J. M. Robillot, B. Leroy and P. A. Gilman for stimulating discussions, also Dr C. H. Barrow for checking our English. $H\alpha$ synoptic maps have been edited by Observatoire de Paris, under the supervision of Dr M. J. Martres. The spectroheliographic plates have been digitized with the PDS microdensitometer (Institut d'optique, Orsay) and analysed using a Vax computer (Paris Observatory). This work was supported by an INAG grant.

Parity-violating energy differences of chiral minerals and the origin of biomolecular homochirality

G. E. Tranter

Theoretical Chemistry Department, University of Oxford, Oxford OX1 3TG, UK

The biochemistry of terrestrial organisms is based on chiral (handed) molecules, with one of the two possible series of enantiomers (mirror-image isomers) being predominant. Specifically, terrestrial biochemistry is homochirally supported by L- α -amino acids and D-sugars to the almost complete exclusion of the enantiomeric D- α -amino acids and L-sugars. This particular homochiral selection may be a result of very small differences between the electronic energies of enantiomeric prebiotic molecules due to the parity-violating weak interactions. The energy differences are, however, so small for simple chiral molecules, that the propagation of homochirality would require a dissymmetry amplification mechanism involving both large quantities of reactants and a long reaction time. An alternative theory, presented here, considering the effects of the parity-violating weak interactions in crystalline enantio-selective prebiotic catalysts, such as the clay silicates, may require considerably less amplification.

The natural competitive selection of a homochiral biochemistry is accounted for generally by elaborations of the stereochemical 'lock-and-key' hypothesis of Fischer¹, but conventionally the terrestrial selection of the L- α -amino acid and D-sugar series over the classically equally viable enantiomeric alternative has been ascribed to chance. The efficient formation of prototype biomolecular polymers during the prebiotic-biotic transition requires the existence of a chemistry approaching homochirality²⁻⁴, and, until recently, the mechanisms proposed for its evolution from a prebiotic racemic geochemistry were equivocal, either of the two enantiomeric homochiral chemistries being selected with equal probability⁵. The violation of parity by the weak interactions provides an alternative, globally consistent, basis for the systematic and determinate selection of the observed homochirality without recourse to chance events.

Through the connection established with electromagnetism^{6,7} the parity-violating weak interactions cause a chiral molecular system and its enantiomer to have slightly inequivalent energies⁸⁻¹¹. Effectively there is a small parity-violating energy difference (PVED), ΔE_{pv} , between the corresponding state energies of a chiral system and its enantiomeric system, which preferentially stabilizes one with respect to the other. The PVED may occur for any chiral system, including transient forms, and can, therefore, manifest itself as an imbalance in the quantities of enantiomeric species in classically racemic equilibrium or as an inequivalence in the rate constants of enantiomeric reactions.

The intrinsic PVED between enantiomeric species and reactions involved in the prebiotic-biotic transition may have specifically selected the known terrestrial homochirality. Recent calculations indicate that the natural L-enantiomers of a series of α -amino acids are stabilized relative to their corresponding unnatural D-enantiomers for the conformations preferred in aqueous media¹²⁻¹⁵. A similar stabilization of the natural enantiomers has been determined for a set of polypeptide/protein fragments in both the α -helix and β -sheet conformations^{12,13} and also for a possible prebiotic reaction to form a precursor of L-alanine¹⁶.

The calculated values of PVED for small chiral molecules are exceedingly small, typically $\sim 10^{-20}$ atomic units (a.u., equivalent to 'hartrees'), although other conceivable systematic chiral influences are generally even weaker. Nonetheless, several kinetic mechanisms that amplify dissymmetry to yield homochirality have been suggested¹⁷⁻²⁰, and it has been determined that even a PVED as small as $\sim 10^{-20}$ a.u. may be sufficient as a selector. However, latest estimates²⁰ of the reaction conditions

required for such an amplification are a lake of volume 4×10^9 litres ($1 \text{ km} \times 1 \text{ km} \times 4 \text{ m}$) which remains homogeneous for some 10,000 yr. While such conditions are possible in the prebiotic era, they must be regarded as exceptional.

The essential difficulty is the minuteness of the intrinsic PVED for small prebiotic chiral molecules. Giant chiral molecules such as polymers, and especially crystal lattices, may have much larger PVED, and may exhibit the resulting dissymmetries at a detectable level without the intervention of amplification mechanisms. For example, the ratio of the numbers of left (*l*) and right (*d*)-handed enantiomorphous crystals (*l/d*), each with *n* unit cells, under chemical equilibrium at temperature *T* is given by

$$l/d = \exp(-\Delta E_{pv}^{(n)}/kT) \quad (1)$$

where *k* is the Boltzmann constant, and the PVED, $\Delta E_{pv}^{(n)}$, is the energy of a (*l*)-enantiomer crystal relative to a (*d*)-enantiomer crystal of the same size (*n*). Taking the first-order approximation^{21,22} that the overall PVED, $\Delta E_{pv}^{(n)}$, has a linear relationship with the number of unit cells, *n*, it can be expressed in terms of the mean PVED per unit, ΔE_{pv}^I , or the advantage factor $\epsilon = -\Delta E_{pv}^I/kT$

$$\Delta E_{pv}^{(n)} = n\Delta E_{pv}^I = -nekT \quad (2)$$

whereupon the dissymmetry ratio becomes

$$l/d = e^{n\epsilon} \approx 1 + n\epsilon \quad |n\epsilon| \ll 1 \quad (3)$$

A corresponding result can be obtained from a kinetic approach using the progressive accumulation model²¹, the PVED then referring to the transition states for crystal growth. The enantiomeric excess, Ω_{crys} , a more convenient measure of the dissymmetry, is related by

$$\begin{aligned} \Omega_{crys} &= \frac{l-d}{l+d} \\ &= \frac{e^{n\epsilon} - 1}{e^{n\epsilon} + 1} \\ &\approx \frac{n\epsilon}{2} \quad |n\epsilon| \ll 1 \end{aligned} \quad (4)$$

For the large number of units, *n*, possible in crystal lattices, even very small non-zero PVED per unit can be enhanced to give a detectable difference in the quantities of left- and right-handed forms of a chiral crystal. Remarkably, such a difference has been documented for naturally occurring quartz²³ where, over a total collection of 16,807 crystals, a 1% enantiomeric excess of *l*-(-)-quartz has been found at all the locations sampled in the Americas, Europe and Asia, with a 90% statistical confidence level that the bias was not a matter of chance. Using a value of the advantage factor $\epsilon \approx 10^{-17}$, appropriate for a unit PVED, ΔE_{pv}^I , of a small chiral structure composed of light atoms ($\sim 10^{-20}$ a.u.), the 1% enantiomeric excess of terrestrial quartz requires $n \approx 10^{15}$ in equation (4). A quartz crystal containing 10^{15} unit cells has the dimensions $\sim 0.1 \text{ mm}$ along each main edge, and is, therefore, very easily attainable. Consequently, the observed natural quartz bias may be evidence of the existence of PVED effects in the physical world, although, at present, it is impractical to perform the necessary calculations of PVED for quartz to confirm this.

An alternative explanation, that the excess of *l*-(-)-quartz was laid down in the post-biotic period and was influenced by the already existing biomolecular homochirality is unlikely. The elevated temperatures associated with the hydrothermal crystallization of quartz are unfavourable, the α -amino acids, for example, racemizing at $\sim 160^\circ\text{C}$ in aqueous solution with a half-life of only a few hours²⁴. Some experimental evidence has also been reported²⁵ on the transference of β -ray dissymmetry to the crystallization of the chiral salt sodium ammonium tartrate

under radiolysis, although its implications for the crystallization of quartz and other minerals are unknown.

Quartz is only one of the many chiral crystalline silicates to be found as minerals of the Earth's surface, and each may exhibit, to differing degrees, analogous enantiomeric excesses. The role of terrestrial minerals, especially the layer-structured silicate clays, in the prebiotic-biotic transition has long been discussed^{26,27}, and interest has recently been furthered by the discovery that clays can absorb mechanical and electromagnetic energy and release it slowly over periods of days²⁸. The most obvious method by which minerals can influence the prebiotic-biotic transition is through their action as catalysts, however to produce an enantiomeric excess in chiral product molecules from racemic/achiral reactants; it is necessary not only to have an enantiomeric excess in the chiral catalyst, but also that it must act enantio-selectively. This enantioselectivity is common, and is illustrated by the preferential adsorption of L-alanine from a racemic mixture by L-(−)-quartz^{29,30}.

For a simple catalytic reaction transforming racemic/achiral reactants into the L- and D-forms of a chiral product with rate constants k^L and k^D respectively, the degree of enantio-selectivity of a particular catalyst can be represented by its enantio-selectivity factor, S

$$S = \frac{k^L - k^D}{k^L + k^D} \quad (5)$$

The enantio-selectivity factors for the left-handed, S_L , and right-handed, S_D , forms of otherwise equivalent chiral catalysts will be different but related by $S_L = -S_D$.

The combination of an enantiomeric excess, Ω_{crys} , of a chiral catalyst (composed of crystals of equal size and surface area), with an enantio-selectivity $S = S_L$ ensures that for such a reaction there is an overall enantiomeric excess, Ω_{prod} , in the numbers of left(L)- and right(D)-handed product molecules formed from a racemic/achiral reactant mixture which is given by

$$\Omega_{\text{prod}} = \frac{L - D}{L + D} = S\Omega_{\text{crys}} \quad (6)$$

If the catalyst is either racemic ($\Omega_{\text{crys}} = 0$) or not enantio-selective ($S = 0$), there is no transference of any chiral bias.

Taking $\Omega_{\text{crys}} = 0.01$, in keeping with the observed 1% enantiomeric excess of terrestrial quartz, and a conservative 0.1% enantio-selectivity ($S = 10^{-3}$), the resulting enantiomeric excess in the chiral product molecules will amount to some 0.001% ($\Omega_{\text{prod}} = 10^{-5}$); this is considerably larger than the corresponding enantiomeric excess due to the inherent PVED of the product molecules themselves, which typically only amounts to $|\Omega_{\text{prod}}| \approx 10^{-17}$ at ambient temperatures.

Whilst the chemistry resulting from chirally biased catalysis is not totally homochiral ($|\Omega_{\text{prod}}| = 1$) it is a great improvement over alternative models, and would require only minor subsequent dissymmetry amplification, which could be achieved by the various proposed mechanisms¹⁷⁻²⁰ using smaller reaction volumes and less time than that required by comparable models. Alternatively, chirally biased catalysis by minerals could form an integral part of a dissymmetry amplification mechanism, further ensuring the rapid propagation of homochirality. Enantio-selective frameworks in possible dissymmetry amplification processes have been experimentally demonstrated by the chirally biased occlusion of α -amino acids into glycine crystals³¹ and also in template-directed oligomerization of biomolecules².

Throughout the above discussion it has been implicitly assumed that the enantiomeric excess and selectivity of the catalyst are such that the bias is towards the observed natural enantiomers of the principal biomolecules rather than their unnatural enantiomeric counterparts. Unfortunately, at present, the validity of this assumption cannot be determined because there is little detailed knowledge of the chemical processes of the prebiotic-biotic transition, and thus the specific relevant catalysts and reactions cannot be identified. Nonetheless, the model's ability to produce relatively large enantiomeric excesses

with ease warrants careful consideration and further investigation.

In conclusion, the indirect globally systematic influence of the weak interactions on the prebiotic-biotic transition, through the parity-violating energy differences in crystalline enantio-selective catalysts, may have specifically selected the observed terrestrial biomolecular homochirality. The role of clays in the prebiotic-biotic transition is still under debate, but their inherent ability to ensure the emergence of a homochiral biochemistry is further evidence in their favour.

New higher primates from the early Miocene of Buluk, Kenya

R. E. F. Leakey* & A. Walker†

* National Museums of Kenya, PO Box 40658, Nairobi, Kenya

† Department of Cell Biology and Anatomy, Johns Hopkins University School of Medicine, Baltimore, Maryland 21205, USA

The important early Miocene site of Buluk, Northern Kenya¹, was re-surveyed in 1983. As a result, the faunal list for this site has been expanded and, as we report here, now includes three hominoid and at least one cercopithecoid species. Some of the species were known previously only from North African sites, but others are typically East African. Only *Proconsul* species have been found before at other East African Miocene sites of equivalent age, but the largest hominoid species from Buluk is an early species of *Sivapithecus*.

The Buluk fossil site (36° 36' E, 4° 16' N) is a small exposure of claystones with coarse sandstone and conglomerate channel fills belonging to the Buluk Member of the Miocene Bakate Formation²⁻⁴. The fossils are found almost exclusively in the channel deposits and are often associated with silicified wood. K/Ar dates on a basalt just above the fossiliferous sediments show that the fossils are older than 17.2 Myr⁴. The 1983 expedition collected new specimens and the faunal list previously given by Harris and Watkins¹ has been expanded and consolidated (see Table 1). Of particular importance is the presence of *Libycochoerus massai* and the crocodile *Tomistoma*, known before only from North Africa. Some fossil fruits were found which

Fig. 1 a-c, Occlusal, right lateral and inferior views, respectively, of KNM-WS 124 (right mandible). d-f, Left lateral, occlusal and anterior views, respectively, of maxilla, KNM-WS 11599. g, h, Occlusal and anterior views, respectively, of mandible, KNM-WS 11599.

are similar to those reported from Rusinga Island as belonging to the form genus *Anonaspermum*⁵.

Three hominoid species are now known from Buluk (see Table 2). A small hominoid about the size of *Micropithecus clarki*⁶ is represented by KNM-WS 12610, a weathered mandible with very worn M_{2-3} . A medium-sized species is known by a right mandibular body with the roots of M_{2-3} and an isolated right M^1 (KNM-WS 12602 and 12608). These remains are about the size of the type specimen of *Kenyapithecus wickeri* from Fort Ternan⁷. On the basis of size there is no doubt that the middle-sized form is a separate species from the better represented large hominoid.

The large hominoid is known by gnathic fragments. The two most complete specimens are described here and illustrated in Fig. 1. KNM-WS 124 is a right mandibular body preserved from the midline at the symphysis to a break behind the M_3 roots.

The crowns of the molars are absent and M_1 was lost in life, as judged from the lack of roots and a large patch of alveolar resorption beneath the distal position of the tooth and beneath M_2 . The base at the symphysis is thickened so that the mental foramen lies near the edge of a hollowed surface under the premolars. The body is deepest under M_2 (38 mm) and is 19 mm thick at this point. The lingual surface is relatively flat, but hollowed in the middle behind M_3 . The buccinator groove is wide (~10 mm) and the take-off of the ramus is twisted so that its surface faces laterally and posteriorly. The external buttress continuing from the anterior edge of the ramus swings in a smooth arc under the molar roots and beneath the mental foramen to continue as the canine ridge. The anterior digastric rugosity is faint. The lengths of M_2 and M_3 have been estimated from their roots at 13 and 15 mm, respectively. This specimen is remarkably similar in parts preserved, size and morphology to GSP 11706 from the Potwar Plateau, Pakistan⁸.

Specimen KNM-WS 11599 is an associated left maxilla and anterior mandible. The mandible fragment has the alveoli for the incisors, roots of the left canine and premolars and the crown of the right canine preserved. The symphysis and the left body to a level under M_1 are present. The symphysis is deep. The alveolar plane angles posteriorly at ~45° and is highly excavated, rising steeply on either side from a midline sulcus. There are clearly defined superior and inferior tori, the latter

being especially well-developed and curving smoothly round to the base. The canine crown is tetrahedral with a small apical dentine exposure; it is rotated so that its long axis lies obliquely. The maximum length is 18.3 mm and the width 13.0 mm. The canine roots are very long and converge inferiorly. The body is distinctly hollowed beneath the premolars and behind the curving canine ridge. The left maxilla contains the canine, P³ and M² crowns and the alveoli and roots of P⁴ and M¹. It reaches to the edge of the incisive foramen medially. This is at a level between the premolars. The upper canine is also long-rooted and stubby-crowned; its root defines a strong canine pillar. The zygomatic process swings abruptly laterally so that there is a deep canine fossa. The canine is 16.5 mm mesiodistally by 14.6 mm mediolaterally, with a height of 15 mm. The P⁴ is bicuspid with a large and high buccal cusp. The remaining buccal half of the M² is hardly worn, has 1.5-mm-thick enamel over the distolingual cusp and a small contact facet for M³. The maxillary sinus extends as a single cavity as far anteriorly as M¹ and hardly evaginates between the molar roots.

On the basis of several features, we believe that this material is distinct from the well-known African early Miocene *Proconsul* species⁹⁻¹². Those features which distinguish it from *Proconsul* are those which compare most favourably with *Sivapithecus*. The most obvious of these are the presence of two mandibular tori, the absence of cingula on the teeth, the strong outward rotation of the canines, the short, deep and strongly buttressed facial skeleton, the deep canine fossa and the posterior position of the incisive foramen.

On the basis of the parts known, it is difficult to offer a differential diagnosis that clearly separates the Buluk material from the genus *Sivapithecus*. A number of authorities have also included middle Miocene hominoids from Europe and Africa in this genus¹³⁻¹⁶. Unfortunately, there seems to be little consensus at present as to the exact status of the species in this genus, the hypotheses of most workers being different. Under these circumstances we believe it to be most useful to assign the large Buluk species to *Sivapithecus*. There is a close resemblance to larger specimens from India and Pakistan which have been placed in *Sivapithecus indicus*⁸ and from Turkey which have been placed in *Sivapithecus metei*¹³ or *S. indicus*¹⁷. *Sivapithecus* as presently being used by many workers almost certainly includes many widely dispersed species of early to middle Miocene hominoids which are similar in jaw and tooth morphology and which are representatives of a long-lived radiation, but whose exact cladistic relationships are not yet clear. Members of this genus were present in Africa over 17 Myr ago and persisted at least in Asia until about 7.5 Myr ago¹⁸. The Buluk species of *Sivapithecus* extends the time range of this genus back into the early Miocene. The similar and well-known *S. indicus* from the U level of the Potwar Plateau¹⁹ at close to 8 Myr is only half as old as the Buluk species. A single fragment of maxilla has previously been assigned to this genus⁹, but this specimen's provenance in East Africa is unknown. It is the type specimen of *Sivapithecus africanus*⁹ and it could be as old as 18 Myr if it is, as originally thought, from Rusinga Island. Others have suggested that the specimen came from Maboko²⁰, which would date it roughly equivalent to Fort Ternan, a site from which were obtained fragmentary specimens which have also been assigned to this genus¹⁶. As recently as 1978 this maxilla was placed in *Proconsul nyanzae* by the same authorities who now call it *Sivapithecus*²¹.

The unequivocal presence of *Sivapithecus* in Africa over 17 Myr ago also gives a new slant to the debate on hominoid origins. The presence of putative *Pongo* ancestors¹³ at 11–8 Myr in Asia was thought to be consistent with divergence dates between *Pongo* and African hominoids calculated from molecular evidence²². If there is indeed a unique ancestral relationship between the Buluk species and the later Asian ones, the fossil and molecular evidence are no longer congruent because the divergence time would be twice as great.

The recognition of *Pongo*-like features in Asian *Sivapithecus* species²² has led many authorities to place all similar fossil

species in the same clade and, by so doing, removed them from candidacy as either African ape or human ancestors. We believe this to have been premature. Leaving aside the possibility that the Buluk species represents an extinct lineage completely independent of Asian *Sivapithecus*, it is more likely in our opinion that the *Sivapithecus* morphology was present in the early ancestors of all great apes and hominids. It has become increasingly clear that is difficult to recognize primitive or derived features in these hominoids, one authority recently uniting *Sivapithecus*, *Pongo* and *Homo* in a single clade distinct from the African ape clade²³. Rather than conclude that the Buluk *Sivapithecus* represents the beginning of the *Pongo* clade in Africa over 17 Myr ago, we view it as an early species of a genus from which both African apes and hominids could be derived. The existence of such an old specimen of *Sivapithecus* does not necessarily say very much about the divergence time of the African and Asian hominoid clades.

We thank the Government of Kenya and the Governors of the National Museums of Kenya. The research was financed by the National Geographic Society of Washington, DC, the Garland Foundation and the National Museums of Kenya. We thank Bw. Kamoya Kimeu and his prospecting team for their invaluable help. Drs M. G. Leakey, I. McDougall, D. R. Pilbeam and R. Watkins helped in many ways.

Age of hominoid-bearing sequence at Buluk, northern Kenya

Ian McDougall* & Ronald T. Watkins†

* Research School of Earth Sciences, Australian National University, PO Box 4, Canberra, ACT 2601, Australia

† Department of Geology, University of St Andrews, College Gate, St Andrews, Fife, Scotland KY16 9ST, UK

In northern Kenya, detrital terrigenous sediments of the Buluk Member of the Bakate Formation contain an important vertebrate fauna, which includes material from three hominoid species, one of which has been assigned to the genus *Sivapithecus* and is described elsewhere in this issue¹. Here we report K–Ar age data on feldspars from volcanic rocks in the area that show the Buluk Member sediments were deposited between 16 and something more than 17.2 Myr ago in the late early Miocene.

The area from which the fossils were recovered lies in the upper Bakate Valley, 45 km east of Ileret and Lake Turkana in Kenya (Fig. 1). The geology has been described previously^{2,3}. Briefly, the sequence dips ~6° to the south-west (Fig. 2), and

Fig. 1 Map showing location of area in northern Kenya.

consists of volcanic rocks, volcanoclastic sediments and normal detrital sediments; a composite stratigraphical section is given in Fig. 3. The Bakate Formation comprises basalts of the Irile Member, overlain by the mainly sedimentary Buluk Member, in turn overlain by basalts of the Il Jimma Member, and is succeeded disconformably by volcanoclastic sediments and ignimbrites of the Gum Dura Formation. The Buluk Member in its type section, near the hominoid locality (Fig. 2), is ~50 m thick. The lower 30 m of the Member consists predominantly of soft, poorly indurated clays, silts, sands and conglomerates of fluvial aspect. Vertebrate fossils have been recovered from sandstones, sandy siltstones and pebble conglomerates over ~15 m of the section (Fig. 3). Locally within the Buluk Member, just above the vertebrate bearing sediments, there is an essentially aphyric basalt flow ~2 m thick. The upper part of the Buluk Member, up to 20 m thick, consists of redeposited air-fall pantelleritic tuffs which are remarkably free of detrital components.

Samples for isotope dating were collected from several volcanic units in the sequence (Fig. 3) so that the reliability of the measurements could be assessed by comparison with the known stratigraphical order. Unfortunately, no suitable samples of basalt from the Irile Member were available for dating.

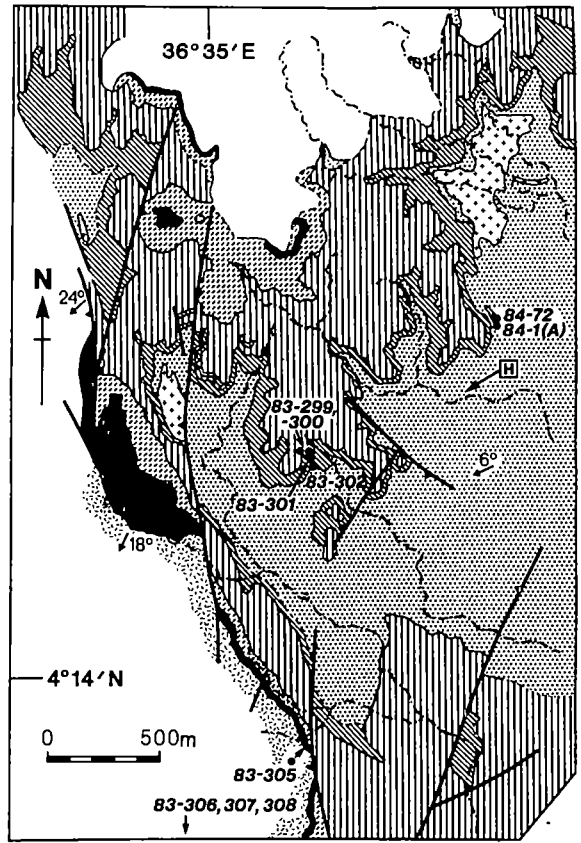

Fig. 2 Simplified geological map of the Buluk vertebrate fossil locality showing collection sites of samples used for dating (●) and of the hominoid specimens (H). Stratigraphical division and key is given in Fig. 3.

In all cases, separation of high-temperature volcanic feldspar provided suitable material for isotope dating by the conventional K-Ar method. Alkali feldspar of high purity was obtained from ignimbrite samples of the Gum Dura Formation and two tuff samples from the upper part of the Buluk Member, using

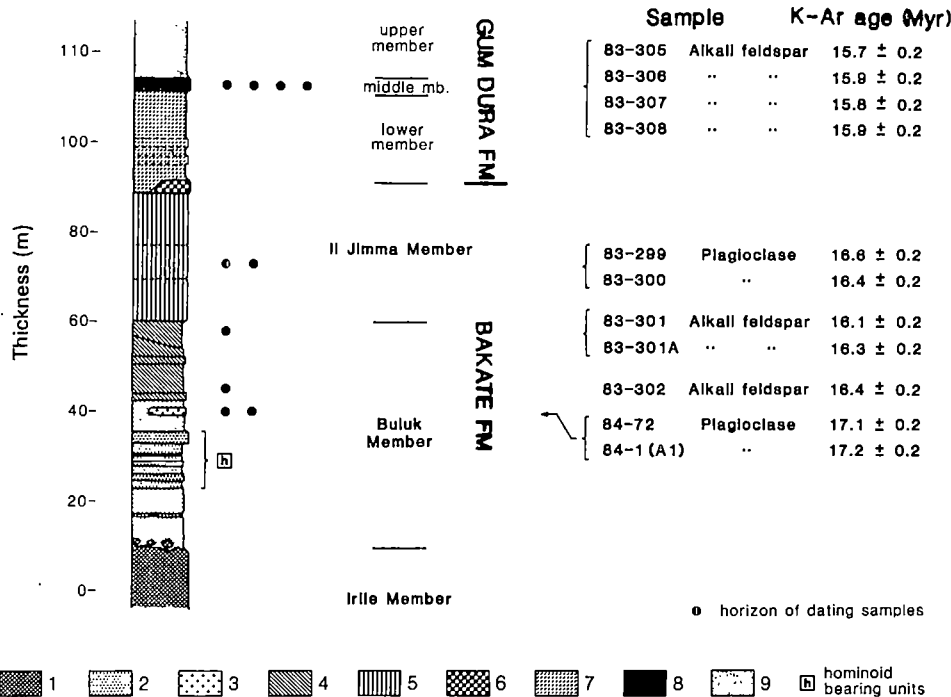

Fig. 3 Generalized stratigraphic section showing the units exposed at the Buluk fossil locality, the position of the dated samples in the sequence and their measured ages. 1, Deeply weathered porphyritic feldspar-phyric basalt lavas; 2, fluvial claystones, siltstones, sandstones and conglomerates of terrigenous origin; 3, thin aphyric or finely porphyritic basalt lava flows; 4, water redeposited air-fall pantelleritic tuffs; 5, fine-grained aphyric basalt lavas; 6, localized hydrothermal deposits of travertine and sinter; 7, pyroclastic pantellerites including air-fall deposits (largely reworked), poorly welded ignimbrites, and volcanic breccias; 8, strongly welded pantelleritic ignimbrite; 9, generally poorly welded pantelleritic ignimbrites.

Table 1 K-Ar ages on feldspars from ignimbrites, tuffs and basalts from the Buluk area, northern Kenya

Sample no.	Sample	Grid reference HBH—	K (wt %)	Radiogenic ⁴⁰ Ar (10 ⁻¹⁰ mol g ⁻¹)	100 rad. ⁴⁰ Ar	Calculated age (Myr ± 1 s.d.)	Average age (Myr ± 1 s.d.)

* Ar extraction done together with 1.0 g of essentially zero age basalt as a flux.

standard heavy liquid and magnetic separation techniques. No detrital contamination was seen in the tuffs. All the alkali feldspars were fresh and limpid, with no evidence of unmixing. Basalt samples collected from the flow within the Buluk Member and from the Il Jimma Member were essentially aphyric, although the Buluk basalt contained sparse plagioclase and altered olivine microphenocrysts. Unaltered plagioclase as thin laths, averaging 0.1–0.2 mm in length, is the most important constituent of the basalts, together with lesser amounts of pyroxene, iron oxide, some olivine and up to ~10% of green mineraloid, clay or chlorite. Because of the presence of alteration products, the samples were judged to be unsuitable for dating as whole rocks, and instead the plagioclase was separated, albeit with difficulty because of its small grain size. To obtain sufficiently good separates, the concentrates were treated briefly in dilute HF to remove mineraloid and clay in composites with the feldspar. The grain size of the plagioclase separates averaged ~50 μm. The K–Ar age measurements were made according to procedures described previously^{4,5} using flame photometry for K and isotope dilution for Ar. The Ar isotope measurements were carried out in a VG-Isotopes MM1200 mass spectrometer operated in the static mode online with a computer. As noted earlier⁵, it is difficult to extract Ar quantitatively from volcanic alkali feldspars. Each sample, contained within a Mo crucible in a water-cooled silica glass bottle attached to the high-vacuum extraction line, was held at ~1,600 °C for 40–60 minutes using radiofrequency heating. In some cases it was suspected that there was incomplete Ar recovery, despite the high temperature

of extraction. Consequently, some replicate runs were made using 1.0 g of a very young basalt as a fluxing agent with the feldspar, following the suggestion of McDowell⁶. The basalt (sample no. 83-229) used as flux contained <7.0 × 10⁻¹⁴ mol g⁻¹ radiogenic Ar. Quantitative extraction of Ar from plagioclase seems to be much less of a problem compared with alkali feldspar. Results are given in Table 1, arranged in stratigraphical order. Reproducibility of both K and Ar measurements is generally better than 1%, so that the overall precision is ~1%. The average age for each sample is reported with a minimum error of 1%, as the combined uncertainties in the calibration of the Ar tracer and K standards are at this level. Several of the earlier Ar results for alkali feldspars have been omitted from Table 1, as replicate measurements clearly showed that there had been incomplete extraction of Ar. In one case where this was suspected, the crucible was heated again at an even higher temperature (>~1,700 °C) for a further 45 min, and additional radiogenic Ar was detected, ~4% of the total radiogenic Ar. Although the four alkali feldspars separates from the Gum Dura ignimbrites averaged 1.0% higher radiogenic ⁴⁰Ar when the basalt flux was used compared with the results without the flux, we regard the agreement as satisfactory. The consistency of results from samples from the same or closely related stratigraphical levels (Table 1), together with an overall decrease in age upwards through the sequence from 17.2 ± 0.2 to 15.8 ± 0.2 Myr (Fig. 3), provides confidence that the measured ages closely reflect the time since crystallization of these volcanic rocks and the deposition of the associated detrital

sediments. However, detailed examination of the results reveals some minor inconsistencies that must be addressed.

Alkali feldspar separated from four samples of ignimbrite from the middle member of the Gum Dura Formation yield completely concordant ages, with a mean of 15.8 ± 0.2 Myr (Table 1). The four samples were collected at different localities extending as far as 4 km south of the map area; only the most northerly locality is shown in Fig. 2. The member comprises two welded ignimbrite sheets, and the fact that the samples are from the same or closely related welded ignimbrite units is supported by the concordant ages and the similarity of the K contents of the alkali feldspars. Because of the unaltered nature of the feldspars, the excellent Ar retention properties of volcanic alkali feldspar and the concordancy of the results, we are confident that the measured age is that of crystallization and cooling of the ignimbrites. Thus, 15.8 ± 0.2 Myr is considered a firm younger limit for the age of the Bakate Formation. Ages determined in this study are younger than those of 16.5 ± 0.1 and 16.6 ± 0.1 Myr (recalculated using decay constants used here), derived from $^{40}\text{Ar}/^{39}\text{Ar}$ step-heating experiments by Fitch *et al.*⁷ for alkali feldspar from the two ignimbrites from the middle member of the Gum Dura Formation elsewhere in the area.

Plagioclase from two separate samples of basalt of the Il Jimma Member, collected 50 m apart laterally and probably from the same massive flow, yielded concordant ages of 16.6 ± 0.2 and 16.4 ± 0.2 Myr (Table 1, Fig. 3). Taken at face value, these results suggest the basalt erupted 16.5 ± 0.2 Myr ago, consistent with the age determined for the overlying Gum Dura Formation. Fitch and Miller⁸ reported a K-Ar age of 17.7 ± 1.4 Myr (recalculated) on a whole rock sample of basalt from the Il Jimma Member; the large uncertainty assigned means that the age is indistinguishable from the more precise age given here.

Two separate alkali feldspar concentrates (83-301 and 83-301 A) from a coarse tuff of the Buluk Member, collected ~2 m below the Il Jimma basalt, gave ages of 16.1 ± 0.2 and 16.3 ± 0.2 Myr, respectively. Another alkali feldspar separated from a tuff ~8 m lower stratigraphically and ~2 m above the red claystones of the Buluk Member, yielded a K-Ar age of 16.4 ± 0.2 Myr (Table 1). Although the average of these ages is slightly younger than the mean age measured on the overlying Il Jimma basalts, the difference between them is small and not significant when the errors are taken into account. We conclude from these virtually concordant results that the tuffs of the upper part of the Buluk Member and the basalts of the overlying Il Jimma Member are indistinguishable in age, estimated as 16.4 ± 0.2 Myr.

Plagioclase concentrates from two separate samples of basalt from the same lava flow ~2 m thick within the terrigenous sediments of the Buluk Member, yielded concordant K-Ar ages of 17.1 ± 0.2 and 17.2 ± 0.2 Myr (Table 1, Figs 2, 3). Note that the K contents of the two concentrates differ appreciably, but that the ages agree. We believe the measured age is recording the time of crystallization and cooling of the basalt. Acceptance of this age suggests that >0.5 Myr elapsed between eruption of the basalt flow and the silicic volcanic eruptions that produced the tuffs of the upper part of the Buluk Member. The vertebrate-bearing sediments of the Buluk Member lie just below the basalt (Fig. 3), and as no significant breaks are recognized in the sequence we believe the underlying sediments are unlikely to be very much older.

Thus, the 70-m of sequence sampled yielded K-Ar ages on volcanic feldspars that are generally consistent with the stratigraphy, and in the range 17.2–15.8 Myr, covering a time span of <1.5 Myr (Fig. 3) in the late early Miocene⁹. Vertebrate bearing sediments of the Buluk Member are only a little older than the basalt dated at 17.2 ± 0.2 Myr, and probably no older than 18 Myr. The ages reported here also provide useful data for establishment of a time framework for the stratigraphical sequence found in this part of Kenya².

We thank the National Museums of Kenya and the Government of Kenya for facilitating our field studies, and R. E. F. Leakey for support in the field. R.T.W. was supported by

research grants from National Environmental Research Council. Technical support for the K-Ar dating was provided by M. Cowan, T. Davies, R. Maier and R. Rudowski.

Temporal hyperacuity in the electric sense of fish

Gary Rose & Walter Heiligenberg

Neurobiology Unit, Scripps Institution of Oceanography, University of California at San Diego, La Jolla, California 92093, USA

It has recently become evident that sensory thresholds for certain tasks are lower than those expected from the properties of individual receptors¹. This perceptual capacity, termed hyperacuity, reveals the impressive information-processing abilities of the central nervous system. Although much is known about spatial hyperacuity, temporal hyperacuity has received little attention². Here we demonstrate that an electric fish, *Eigenmannia*, can detect modulations in the timing (phase) of an electrical signal at least as small as 400 ns. Such sensitivity exceeds the temporal resolution of individual phase-coding afferents. This hyperacuity results from a nonlinear convergence of parallel afferent inputs to the central nervous system; subthreshold inputs from particular areas of the body surface accumulate to permit the detection of these extremely small temporal modulations.

Behavioural experiments have demonstrated that certain species of electric fish can perform remarkable analyses of the temporal structure of electrical signals^{3–5}. These animals produce an electrical signal within a species-specific frequency range via an electric organ, and they detect these signals by electroreceptors located throughout the body surface. In the context of one electrosensory behaviour, the jamming avoidance response (JAR), the fish *Eigenmannia* determines whether a neighbour's electric organ discharge (EOD), which is jamming its own signal, is higher or lower in frequency than its own. The fish then decreases or increases its frequency, respectively. To determine the sign of the frequency difference, the fish must detect the modulations in the amplitude and in the differential timing, or temporal disparity, of signals received by different regions of its body surface^{6,7}. The fish is able to shift its discharge frequency in the appropriate direction in at least 90% of all trials for temporal disparities as small as 400 ns (Fig. 1).

Intracellular electrophysiological measurements show that the phase-locked responses of even the best afferent recorded are too jittery to permit such fine temporal resolution⁸. The jitter of this time-locking can be described by its standard deviation. Even the most accurate phase-coders time-lock their spikes with a standard deviation of ~10 μ s (Fig. 2). For a sample period of 300 ms (and thus ~100 EOD cycles), which is the latency of the JAR, the 95% confidence intervals around the mean phase of occurrence of such an afferent's spikes are 2.0 μ s. Yet the fish is able to detect time disparities of several hundred nanoseconds⁸. Statistically, it would appear to be impossible for the fish, using only the information gathered from any single

Fig. 1 Percentage of correct (that is, positive) jamming avoidance responses (JARs) compared with maximal available temporal disparity. Data from three fish are presented. Inset, averaged JARs ($n=10$) for S_2/S_1 ratios of 0.1 (top) and 0.001 (bottom), corresponding to maximal temporal disparities of 80 μ s and 800 ns, respectively. Arrows indicate points at which the sign of the 4-Hz frequency difference was changed.

Methods. An immobilized fish was placed in a two-compartment chamber, and respiration by a constant flow of water through the mouth. The fish's body rested in a slot, lined with silicone grease, thus providing an electrical isolation of >40 dB between compartments (that is, a signal delivered to one compartment would be present in an adjacent compartment at a level less than 1/100th). The fish's own electric organ discharge was eliminated by intramuscular injection of 1–2% Flaxedil and replaced by a sinusoidal signal (S_1) which matched the fish's natural signal in frequency and amplitude. This EOD-replacement signal and the jamming signal (S_2) were presented through the same electrodes located in the head compartment; positive pole in the fish's mouth, negative poles in the water on either side of the fish. S_1 alone was presented in the posterior (tail) compartment; positive pole in the dorsal musculature, negative poles in the water. Thus, phase modulations existed between the signals in these two compartments. With f_1 and f_2 being the frequencies of S_1 and S_2 , a rise in the amplitude of the signal in the head compartment was accompanied by a phase advance or delay of this signal, relative to the signal in the tail compartment, when $f_2 < f_1$ or $f_2 > f_1$, respectively. Since S_1 and S_2 were delivered through the same electrodes, their amplitude ratio (S_2/S_1) was constant at all points in the chamber and equal to the ratio of the outputs of the two function generators that produced them. Thus, the degree of amplitude and phase modulations experienced by the electroreceptors in the head region could be precisely determined. The maximal time disparity, DT, is calculated from the following formula: $DT = aT/2\pi$, where T is the length of the period of S_1 , the signal used to replace the fish's electric organ discharge; S_2 is the jamming signal and a is the amplitude ratio between S_2 and S_1 . While this stimulation arrangement had the advantage of permitting exact determination of the available temporal disparity, it is a less effective means of eliciting the JAR than the multi-chamber arrangement (Fig. 3) or free field conditions (no compartments). The threshold value determined should therefore be considered a conservative estimate. JARs were measured according to the following procedure^{6,8}. The electric organ discharge frequency was determined by recording the spinal volley signal from the electric organ pacemaker via a suction electrode at the tail. This signal was amplified 1,000 times and each discharge triggered a standard square pulse that was fed into a 100-kHz computer-controlled clock for timing analysis. The fish's pacemaker (or would-be electric organ discharge) frequency was then computed. The sign of the 4-Hz frequency difference between the jamming signal (S_2) and the replacement signal (S_1) was changed every 25.6 s by the computer. Positive JAR values indicate a correct JAR (that is, the fish shifted its discharge frequency (DF) in the direction that was appropriate for the stimulus condition at the time); upward shifts for a jamming frequency that was lower and downward shifts for a jamming frequency that was higher. Shifts in frequency were integrated over the period of stimulation, and the mean shift was taken as the JAR measurement.

Fig. 2 *a*, Distribution of spikes around a mean time of occurrence (zero) for a single primary afferent, the most accurate phase-coder recorded. 1,024 spikes were sampled. Bin width is 0.1 μ s. *b*, Electronically generated 'spike-mimics' were recorded by the same equipment used for the neural recordings. The standard deviation of the time of occurrence of these spike-mimics, with reference to the time of their production by the waveform generator, was ~ 700 ns. The neural jitter is, therefore, not a consequence of limitations in the accuracy of measuring spike occurrences.

Methods. Spikes and spike-mimics were recorded with 3 M KCl-filled micropipettes (20 M Ω). Neural recordings were made from the anterior lateral line ganglion of anaesthetized fish. For these recordings, a sinusoidal signal, matching the fish's EOD in frequency and amplitude, was delivered through a positive electrode in the fish's mouth and a negative electrode at the tail. Forty afferents were recorded. The spike-mimic was presented through electrodes in the water. When recorded by the micropipette, these spikes had a similar rise time to that of the steepest portion of the neural spikes (1 mV μ s⁻¹). The membrane potential of the neurone was ~ 80 mV, spikes were 60 mV. Baseline voltage fluctuations were ~ 0.5 mV. This large signal-to-noise ratio reduced the temporal jitter resulting from baseline-voltage fluctuations to well below that commonly experienced in extracellular recordings. The time of occurrence of spikes with reference to each synch pulse from the signal generator, defined as the moment when the steepest portion of the signal passed a trigger level, was measured via a computer-controlled clock with a resolution of 0.1 μ s.

afferent, to reliably shift its frequency in the correct direction when the maximal temporal disparity available is only several hundred nanoseconds.

These findings lead to the prediction that the behavioural threshold should be higher when only a small group of receptors is stimulated, and that hyperacuity results from the convergence, within the central nervous system, of parallel phase-coding channels from sufficiently large areas of the body surface. These notions were tested using a paradigm which enabled us to stimulate selectively particular regions of the body surface (Fig. 3). Jamming avoidance responses could be elicited from stimulation of the body surface within any of the individual compartments, provided the ratio between the amplitude of the jamming stimulus (S_2) and the amplitude of the EOD-replacement signal (S_1) was sufficiently large. For example, an S_2/S_1

ratio of 0.05 produced a strong JAR when the stimulus was delivered exclusively to compartment 3 (Fig. 3*a*). With this ratio the fish experiences a stimulus that has a maximum relative amplitude modulation of 5% and gives rise to a maximal temporal disparity between the signal received by the left and right sides of the body of 28.4 μ s. When the S_2/S_1 ratio was reduced to 0.0016, corresponding to a maximal temporal disparity of 1.8 μ s, no JAR was observed on individual stimulation of compartments 2, 3 or 4 (Figs 3*b*, 4). Simultaneous stimulation of the body surface in these three compartments, however, elicited a strong JAR (Figs 3*c*, 4).

By electronically modulating amplitude and phase independently^{7,9}, one can demonstrate that the resolution of amplitude modulations alone is not the limiting factor in this experiment: the animal fails to increase its JAR to stimulus regimens

Fig. 3 Averaged JARs. A signal (S_1) replacing the fish's own electric organ discharge, and a jamming signal (S_2), which was alternately 4 Hz higher or lower than the replacement signal, were applied to individual compartments (a, b) or simultaneously to all three compartments (c). The amplitude ratio between these two signals, measured lateral to the fish's body, is given on the left-hand side of the figure. Centre (darkest) trace is the mean, traces to either side indicate the standard error.

Methods. An immobilized fish was placed in a multi-compartment chamber. Stimuli were delivered through wires in each of the five compartments. The EOD-replacement signal (S_1) was delivered to each compartment through an electrode in the dorsal musculature and an electrode at the bottom of the compartment, current at any given point in time thus being of the same polarity for all parts of the body surface. The 'jamming signal' (S_2) was delivered, in each chamber, through two electrodes straddling the fish. With this geometry of presentation, current flowed from outside to inside on one side of the body surface, and from inside to outside on the other side, the ventral surface being only minimally affected by the jamming stimulus. Maximal temporal disparity between the signal received by the ventral surface and that received by either lateral surface is DT (as computed according to the formula in Fig. 1), while the maximal temporal disparity between the signals received by the right and left sides is 2DT. The two stimuli to each compartment could be individually delivered or removed by means of a switching network located outside the chamber. By stimulating two adjacent sections of the body, the fish can obtain differential phase information not only by comparing the two sides of the body within the same chamber but also by comparing contralateral sides located in different chambers. No phase differences are available between ipsilateral sides in different compartments. If one assumes linear addition of inputs from separate compartments and a linear relation between the effect of a phase modulation and the size of the contralateral reference area, the simultaneous stimulation of three chambers should yield a total effect of three times the sum of the contributions from individual chambers. This is still far less than was experimentally observed (see Fig. 4). The results were qualitatively similar for all three fish tested.

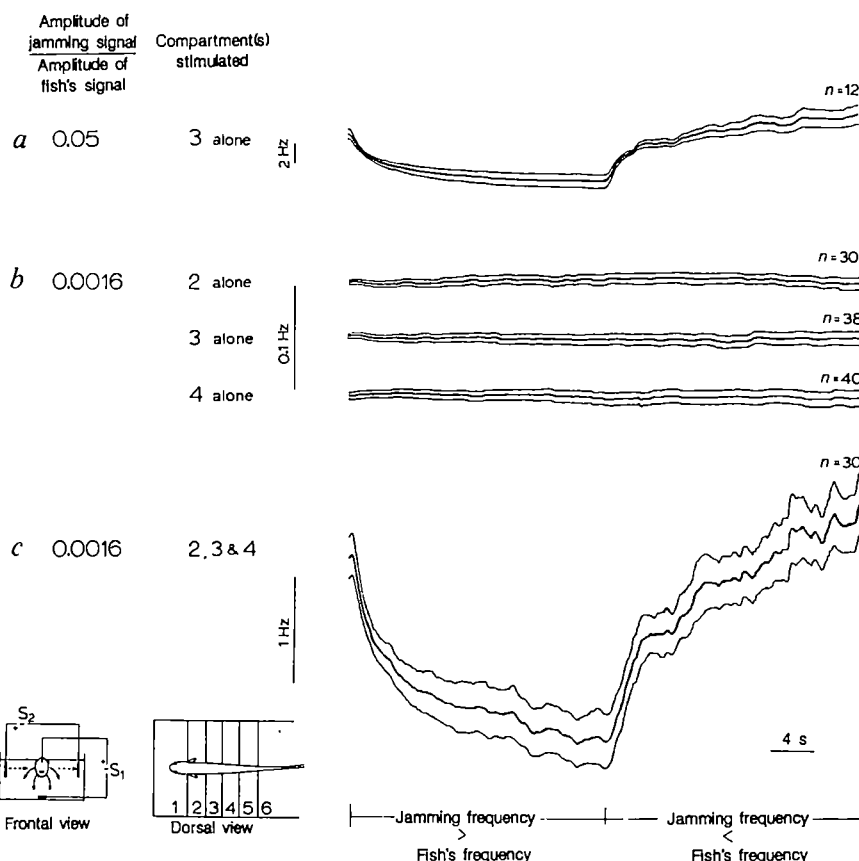

Fig. 4 Mean JAR and 99% confidence intervals for presentation of a signal (S_1) that served as a replacement for the fish's own electric organ discharge, and a jamming signal (S_2), to individual compartments (C2, C3, C4) or simultaneously to various combinations of these three compartments. The ratio between the amplitudes of these two signals is given in each case. Positive JAR values indicate that the fish shifted its electric organ discharge frequency in the appropriate direction (that is, upward when the S_2 frequency is lower than the S_1 frequency and downward for the opposite relation).

involving phase modulations at threshold level even if larger amplitude modulations are presented.

Our results indicate that electroreceptive afferent inputs converge in a nonlinear manner to achieve sensitivity to temporal disparities of several hundred nanoseconds, thus exceeding the interaural time-disparity sensitivity of owls (10 μ s; ref. 10) and of humans (15–20 μ s; ref. 11). In this process, inputs which are individually insufficient to elicit a measurable JAR (even after averaging over 2 h) produce a strong response when combined. This effect is not merely a result of the increase in total stimulus energy being presented to the fish because the amplitudes of S_1 and S_2 can be increased, while keeping their ratio constant, without altering the single-compartment response.

This temporal hyperacuity resembles hyperacuity in spatial vision in that the exquisite sensitivity is dependent on the presence of a reference point. In vision, the detection of small spatial modulations of a dot, line or edge is enhanced when a reference feature, displaced from the modulated feature, is made avail-

able¹². Similarly, for detection of small modulations in the timing of a signal, *Eigenmannia* requires a reference signal; the fish compares the timing of the signal in one region of the body surface with that in another region⁷.

Mammalian neural crest cells participate in normal embryonic development on microinjection into post-implantation mouse embryos

Rudolf Jaenisch

Whitehead Institute for Biomedical Research and
Department of Biology, Massachusetts Institute of Technology,
Nine Cambridge Center, Cambridge, Massachusetts 02142, USA

The production of chimaeric mice by aggregating pre-implantation mouse embryos¹ or by injection of cells into the blastocyst² has been of great value in analysing the regulation of early mammalian development and in dissecting the relationships of early cell lineages^{3,4}. While the totipotent cells of the pre-implantation embryo can be grown *in vitro* and thus are readily accessible to experimental manipulation, this is not possible after the embryo has implanted into the uterus. This problem has severely hampered the analysis of cell migration and of cell lineage relationships in later stages of mammalian development. In contrast, the chicken embryo can be manipulated experimentally throughout embryogenesis and this has made the bird a favourable system for studying patterns of cell migration in the development of higher vertebrates⁵⁻⁷. In mammals, the introduction of retroviruses^{8,9} and haematopoietic cells¹⁰ has provided two means of probing post-implantation development by direct intervention. I report here that cultured neural crest cells, when microinjected into 9-day-old mouse embryos, can migrate over considerable distances and participate in normal development, and the resulting chimaeric animals show pigmentation derived from the donor cells in hair and iris. The introduction of cells into post-implantation embryos may provide the means of studying patterns of cell migration in mammalian development at a level of sophistication which so far has been restricted to the chicken system.

Neural crest cells originate from the neural folds and begin migrating into many regions of the embryo at the time of neural tube closure^{5,11}. Experiments with amphibia^{12,13} and chickens^{5,11,14,15} have shown that this embryonic population of cells gives rise to an astounding variety of different cell types, including sensory and autonomic ganglia, facial bone and cartilaginous structures, stroma of various secretory glands, and the pigment cells of the skin. When neural tubes from mid-gestation mouse embryos are explanted *in vitro*, cells which resemble morphologically the well-characterized chicken neural crest cells begin to migrate from the explant¹⁶. After several days in culture, cells begin to synthesize catecholamines and become dopa-positive, indicating their differentiation into adrenergic and prepigment cells¹⁶. Pigment formation, however, has never been observed in explants of murine, in contrast to chicken neural crest cells^{17,18}. In the present study I investigated whether explanted neural crest cells would become functional melanocytes when microinjected into developing post-implantation mouse embryos.

C57BL/6J mouse embryos were isolated at day 8.5 of gestation (5–15-somite stage) and were explanted as described in Fig. 1 legend. Cells began to migrate from the explants within 24 h and the neural tubes were detached from the dishes with tungsten needles after 2 or 3 days. Figure 1 shows a typical culture at 3 days after explantation. The migrating cells have a similar morphology to that described for neural crest cells isolated from chickens¹⁹ and mice¹⁶. Cells of neural crest morphology were seen predominantly at the edges of the migrating cells, whereas in the centres of the outgrowths extensive differentiation occurred with increasing time of culture, resulting in cells of epithelial and neuronal morphology. Further characterization of the different cell types was not attempted.

For microinjection, individual cultures were trypsinized at 3–13 days after explantation, and the cells were concentrated

Fig. 1 *In vitro* culture of explanted neural tubes. The figure shows phase-contrast photomicrographs of cells migrating from the neural tube at 3 days after explantation. *a*, $\times 34$; *b*, $\times 112$.

Methods. C57BL/6J mouse embryos were isolated at day 8.5 of gestation (day of vaginal plug = day 0 of gestation). The embryos were freed of placenta and fetal membranes and incubated in HEPES buffer containing 1% trypsin at 5°C for 20–30 min¹⁷. Enzyme treatment was stopped by washing the embryos twice in HEPES buffer containing 10% fetal calf serum (FCS), and the neural tubes were dissected from the embryos under a dissecting microscope. The neural tubes were carefully freed of somites and all surrounding tissues and between five and eight tubes were placed in a 2-cm tissue culture dish which had been coated previously with collagen (Vitrogen) or gelatin (0.5% solution for 1 h); they were then cultured in DMEM containing 5% FCS and 5% horse serum.

by centrifugation and resuspended in 25–40 μ l of DMEM (Dulbecco's minimal essential medium) containing 10% calf serum. The total number of cells obtained per culture varied between 2×10^4 and 2×10^5 . The cells were microinjected into recipient BALB/c embryos at day 8.25, between day 8.75 and 9.25, or at day 9.75 of gestation essentially as described previously^{8,9}. Briefly, the pregnant mice were anaesthetized and laparotomy was performed by a long ventral incision. The uterus was held with a sharp forceps and cells were microinjected into individual embryos by introducing the micropipette into the ventral third of the decidual swelling. Approximately 0.1–0.5 μ l of liquid, containing 50–300 cells, was injected per embryo. Table 1 shows that approximately 60% of the injected embryos survived to adulthood.

On visual inspection of the resulting animals, I found that approximately 15% of the mice derived from embryos injected with neural crest cells between days 8.75 and 9.25 of gestation showed evidence of a pigment contribution from the donor cells

(Table 1). In contrast, none of 121 animals derived from embryos injected at day 8.25, and none of 71 animals injected at day 9.75 of gestation showed visible pigmentation. The fraction of chimaeric animals obtained, however, was strongly dependent on the age of the neural crest cell cultures. Table 2 shows that cells from 3–5-day-old cultures resulted in more than 30% chimaeric mice, while this fraction decreased to approximately 1% when cells from 11–13-day-old cultures were used for injection. This result suggests that the fraction of undifferentiated neural crest-like cells shown in Fig. 1, rather than the more differentiated cell types which accumulate with prolonged culture, give rise to pigmentation in the chimaeric mice.

Figure 2 shows typical examples of chimaeric mice. Pigmented hair was found in either the head or posterior trunk region, but never in the upper mid-trunk region or the forelimbs (see Table 3). Most chimaeras had pigmented hair in the head region which typically covered a symmetrical area extending laterally from the mid-dorsal line to both sides (Fig. 2a–c). Approximately 30% of the chimaeras were pigmented in the posterior trunk region, including the hindlimbs (7 animals; Fig. 2c, d) or the tail (3 animals; Fig. 2b). The pigmented area in the posterior trunk region frequently showed a sharp demarcation at the mid-dorsal (Fig. 2c) or mid-ventral line. However, pigmentation was not restricted to the epidermis. Microscopic inspection revealed extensive pigmentation of the iris in 10 of the 22 animals exhibiting head chimaerism. The pigment appeared to radiate in sections from the pupil to the back of the eye (Fig. 2e). Similarly, pigmented cells appeared to radiate from the optic nerve to the equator of the eye when viewed from the back (Fig. 2f). Histological examination revealed that the pigmented cells were localized in the choroid and not in the retina (U. Dräger, personal communication). This result is consistent with earlier observations indicating that the pigment of the mesodermal iris and of the choroid is derived from neural crest cells^{20,21} and not from the central nervous system (CNS), which gives rise to the pigmentation of the retina. Table 3 summarizes the types of pigment distribution seen in the 31 chimaeras. Three classes of animals were observed (types A, B and C). Pigment was restricted to the head area in 19 animals and to the posterior trunk in 9 animals. Three animals, however, exhibited pigmentation of the head as well as of the posterior trunk (type C in Table 3; compare with Fig. 2c).

The phenotype of the chimaeras indicates that neural crest cells which have been introduced into an embryo at late stages of development can participate in normal morphogenesis. How do the injected cells reach their position in the skin and iris? Because the embryo cannot be visualized at the time of injection, the pathway of donor cell migration can only be deduced from the phenotype of the chimaeras. Principally, after successful injections resulting in chimaeric mice, the cells may have been deposited either inside the embryo proper or outside it, in the extraembryonic cavities—that is, the yolk or amniotic cavity. After injection, donor cells may have migrated along aberrant pathways, for example in the trough of the exocoelomic cavity, or they may have followed normal pathways of neural crest cell migration in the dermis.

The following considerations argue against the donor cells

Fig. 2 Chimaeras resulting from successful injection of neural crest cells. a, Littermates (2 weeks old) with head pigmentation. b, Littermates (2 weeks old) with pigmented head and tail. c, Animal with extensive pigmentation in head, posterior trunk and hindlimbs. Note the sharp demarcation at the mid-dorsal line. d, Animal with two pigmented hindlimbs. Note the fine line of interspersed pigmented hair extending from the mid-dorsal line to both feet. e, Pigmentation in the iris. f, Pigmentation in the choroid as viewed from the back of the eye.

Methods. BALB/c mouse embryos were microinjected between days 8.75 and 9.25 of gestation with *in vitro*-cultured neural crest cells of C57BL/6J origin as described in the text and for Table 1.

having been deposited in the embryo proper or having migrated along abnormal pathways. (1) Pigmented cells always originated in the mid-dorsal line and when colonizing the head region, migrated to both sides mediolaterally, giving rise to symmetrical patches (see Fig. 2a–c). In all cases of distal pigmentation in the posterior trunk region, a fine line of interspersed pigmented hairs extending from the mid-dorsum down to the hind foot revealed the migratory path (see Fig. 2d). (2) Pigmentation was restricted to the head and posterior trunk region and was never seen in the anterior trunk or forelimbs, even in animals that were pigmented at the anterior as well as at the posterior end (see Fig. 2c, Table 3). (3) Both the radial pigmentation in the iris and choroid and the sharp demarcation of pigmentation along the mid-dorsal and mid-ventral lines seen in many of the chimaeras reveal the normal migratory pattern of neural crest cells and resemble the patterns observed in allophenic mice^{1,2,4,22}.

To explain the generation of chimaeric animals, it is reasonable to assume that the injection pipette has to penetrate the

Table 1 Results of injection of post-implantation embryos (BALB/c) with neural crest cells (C57BL/6J)

Age of embryos (days of gestation)	Injected	No. of embryos surviving to weaning	With pigment contributions
8.25	213	121 (57%)	0
8.75–9.25	340	212 (62%)	31
9.75	118	71 (60%)	0

BALB/c embryos were microinjected at day 8.25, between days 8.75 and 9.25, and at day 9.75 of gestation, with neural crest cells obtained from C57BL/6J neural tubes and cultured *in vitro* as described in Fig. 1 legend.

Table 2 Pigment contribution in BALB/c mice injected with C57BL/6J neural crest cells between days 8.75 and 9.25 of gestation

Age of neural crest culture	No. of animals	
	Total	With pigment
3–5 days	83	28
6–8 days	35	2
11–13 days	84	1

Injections with cells from 3–5-day-old cultures were performed at day 8 between 17:00 and 20:00 h, at around midnight on the same day, and between 06:00 and 08:00 h on day 9; no significant difference in the fraction of chimaeras obtained was observed. Most of the injections with cells from older cultures were performed at day 8.75.

Table 3 Pigment distribution in neural crest injection chimaeras

Type	No. of animals	Head, eyes	Pigment contribution	
			Anterior trunk and forelimbs	Posterior trunk (back, hindlimbs, tail)
A	19	+	—	—
B	9	—	—	+
C	3	+	—	+

yolk sac and probably the amnion, but not the embryo proper. The phenotype of animals of type C (Table 3) actually indicates that after a single injection the cells have migrated to both (opposite) ends of the animals while sparing the anterior and mid-trunk region. This suggests that the cells, after having been deposited in the amniotic cavity, are restricted as to where they can enter the embryo proper. The anterior and posterior neuropores, which close at the 18- and 30-somite stage respectively, and thus much later than the neural tube in the mid-trunk region, may serve as the points of entry. Having entered the embryo, the cells appear to have followed the normal pathways of neural crest cell migration from the mid-dorsal line mediolaterally, as indicated by the similarities of the pigment patterns seen in injection chimaeras to those of allophenic mice. If correct, this would indicate that neural crest cells, even when deposited outside their normal pathways of migration, can penetrate the epithelium and migrate to their normal locations in the epidermis to form functional pigment cells. The restriction of pigment to the mid-dorsum in many chimaeras may indicate, however, that the amelanotic host melanoblasts can interfere with the migration of the donor cells or with their 'homing-in' on the epidermis. Earlier observations have indeed demonstrated that amelanotic melanoblasts can prevent normal melanoblasts from entering the epidermis²³.

Only embryos injected between days 8.75 and 9.25 of gestation developed into animals with pigment chimaerism, whereas none of the embryos injected 12 h previously or 12 h later gave rise to pigmented mice. It is possible that the embryo at day 8.25 is physically too small to allow introduction of cells into the yolk sac and amnion. At day 9.75 of gestation, the neural tube is already closed at the anterior end, thus preventing the injected cells from entering the embryo at that site; the posterior neuropore may still be open, but technical difficulties rather than developmental constraints may interfere with successful colonization from that end at the later stage.

The manipulation of post-implantation mouse embryos by cell injection has great potential for the analysis of patterns of cell migration in early stages of mammalian morphogenesis under *in vivo* conditions. It would be particularly interesting to investigate whether other migratory cells such as primordial germ cells, which normally migrate from the allantois to the genital ridge between days 8 and 12 of gestation²⁴, could colonize an embryo after microinjection. The results described here suggest that the post-implantation embryo can be used to analyse cell interactions at critical stages of development. For example, cell surface antigens have been implicated as being important in cell adhesion and morphogenesis²⁵. Retroviral vectors²⁶ could be used to transfer cellular genes, such as those coding for cell surface antigens, into the cells prior to injection to elucidate the role of these antigens in cell migration and homing. This approach may allow us to study the cell-cell interactions in mammalian development that are crucial for morphogenesis and which, so far, have not been amenable to experimental analysis.

I thank Dr J. Price for advice in isolation and culture of neural crest cells, Dr U. Dräger for help in photography and sectioning of mouse eyes, and Dr C. Cepko for a gift of serum. This work was supported by grants HD-19105 from the NIH and PO1-CA38497 from the National Cancer Institute.

Insulin rapidly stimulates tyrosine phosphorylation of a M_r -185,000 protein in intact cells

Morris F. White, Ruth Maron & C. Ronald Kahn

Research Division, Joslin Diabetes Center and Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, Massachusetts 02215, USA

Phosphotyrosine-containing proteins are minor components of normal cells^{1,2} which appear to be associated primarily with the regulation of cellular metabolism and growth^{3,4}. The insulin receptor is a tyrosine-specific protein kinase^{5,6}, and one of the earliest detectable responses to insulin binding is activation of this kinase and autophosphorylation of its β -subunit⁷⁻⁹. Tyrosine autophosphorylation activates the phosphotransferase in the β -subunit and increases its reactivity toward tyrosine phosphorylation of other substrates^{10,11}. When incubated *in vitro* with [γ -³²P]ATP and insulin, the purified insulin receptor phosphorylates various proteins on their tyrosine residues¹²⁻¹⁶. However, so far no proteins other than the insulin receptor have been identified as undergoing tyrosine phosphorylation in response to insulin in an intact cell. Here, using anti-phosphotyrosine antibodies, we have identified a novel phosphotyrosine-containing protein of relative molecular mass (M_r) 185,000 (pp185) which appears during the initial response of hepatoma cells to insulin binding. In contrast to the insulin receptor, pp185 does not adhere to wheat-germ agglutinin-agarose or bind to anti-insulin receptor antibodies. Phosphorylation of pp185 is maximal within seconds after exposure of the cells to insulin and exhibits a dose-response curve similar to that of receptor autophosphorylation, suggesting that this protein represents the endogenous substrate for the insulin receptor kinase.

To identify any phosphotyrosine-containing proteins which might appear in cells as a consequence of insulin binding, the well-differentiated and insulin-sensitive hepatoma cell line Fao^{17,18} was labelled with ³²P-orthophosphate for 2 h¹⁹. Then the cells were either treated with 100 nM insulin or left untreated and the monolayers were solubilized with Triton X-100 as described in Fig. 1 legend. Purification of the resulting extract by wheat-germ agglutinin(WGA) chromatography and immunoprecipitation with anti-insulin receptor antibody showed

Fig. 1 Purification of phosphotyrosine-containing proteins from ^{32}P -orthophosphate-labelled Fao cells by immunoprecipitation with anti-insulin receptor and anti-phosphotyrosine antibodies. *a-d*, WGA-purified extracts immunoprecipitated with anti-receptor antibody (*a, b*) or anti-phosphotyrosine antibody (*c, d*). *e-h*, Whole-cell extracts immunoprecipitated with anti-phosphotyrosine antibody (*e, f*) or with anti-phosphotyrosine antibody, followed by anti-receptor antibody (*g, h*).

Methods. Fao cells were grown in plastic tissue culture dishes (15-cm diameter) containing 30 ml of RPMI 1640 medium (Gibco) supplemented with 10% fetal bovine serum (Gibco); 12 h before each experiment, the culture medium was changed to serum-free RPMI 1640. Confluent Fao cells were labelled for 2 h in 10 ml of phosphate-free and serum-free RPMI 1640 medium containing carrier-free ^{32}P -orthophosphate (0.5 mCi ml $^{-1}$; NEN). Cells were incubated without (-) or with (+) insulin (100 nM) at 37°C for 1 min, then the experiments were stopped quickly by removing the incubation medium and freezing the cell monolayers with liquid nitrogen. The monolayers were thawed and solubilized immediately at 4°C with 2 ml of a solution containing 50 mM HEPES pH 7.4, 1% Triton X-100, 10 mM sodium pyrophosphate, 100 mM sodium fluoride, 4 mM EDTA, 2 mM sodium vanadate, 1 mg ml $^{-1}$ aprotinin, and 2 mM phenylmethylsulphonyl fluoride. A supernatant of the whole-cell extract was prepared by scraping the cells from the dishes and sedimenting the insoluble material by centrifugation at 50,000 r.p.m. in a Beckman 70.1 Ti rotor for 60 min. WGA-purified extracts were obtained by applying the supernatant to a 0.5-cm diameter disposable column (BioRad) containing 0.2 ml of WGA-agarose (Vector). The agarose was washed with 100 ml of 50 mM HEPES pH 7.4 containing 0.1% Triton X-100, 10 mM sodium pyrophosphate, 10 mM sodium fluoride, 4 mM EDTA and 2 mM sodium vanadate, and the bound glycoproteins were eluted with two 0.5-ml portions of this wash solution containing 300 mM *N*-acetylglucosamine (Sigma). Specific immunoprecipitates were obtained from WGA-purified extracts (*a-d*) or from whole-cell extracts (*e-h*) using anti-phosphotyrosine antibodies prepared according to the method of Pang *et al.*³⁴ or anti-insulin receptor antibodies (B2) obtained from patients³¹. After incubation with the extract at 4°C for 2 h, the antibodies were immobilized on Pansorbin (Calbiochem) and the precipitates were washed three times with a solution containing 50 mM HEPES, 1% Triton X-100 and 0.1% SDS. Proteins were eluted from the phosphotyrosine-antibody complex by addition of 10 mM *p*-nitrophenylphosphate to the wash solution⁹ and from the anti-receptor antibody with SDS-polyacrylamide gel electrophoresis (PAGE) sample buffer³¹. The eluted proteins were reduced with 100 mM dithiothreitol (DTT; BioRad) and the phosphoproteins were separated by SDS-PAGE on 7.5% resolving polyacrylamide gels as described previously³². The phosphoproteins were identified by autoradiography (6 h exposure) of the stained and dried gels using Kodak X-Omat film and an intensifying screen. The WGA-purified extract was immunoprecipitated with anti-receptor antibody (*a, b*) or anti-phosphotyrosine antibody (*c, d*). The whole-cell extract was immunoprecipitated with anti-phosphotyrosine antibody and the precipitated phosphoproteins were either separated by PAGE (*e, f*) or immunoprecipitated a second time with anti-receptor antibodies before SDS-PAGE (*g, h*).

Fig. 2 Dose-response curve for effect of insulin on tyrosine phosphorylation. Labelled Fao cells were incubated in the presence of insulin for 10 min. Phosphoproteins were immunoprecipitated from the whole-cell extracts with the anti-phosphotyrosine antibody, eluted, separated by SDS-PAGE and identified by autoradiography as described in Fig. 1 legend. The intensities of pp185 (●) and the β -subunit (■) were measured by scanning densitometry and are presented as a percentage of the maximum stimulation. The maximum values, measured at 100 nM insulin, were 603 and 1,680 for pp185 and the β -subunit, respectively. The background measured in the absence of insulin has been subtracted.

a single insulin-stimulated phosphoprotein of M_r 95,000. This band was present in the basal state and increased about fourfold during insulin stimulation for 1 min (Fig. 1*a, b*). We have shown previously that this band corresponds to the β -subunit of the insulin receptor which undergoes tyrosine phosphorylation in response to insulin stimulation^{7,9,19}. When the WGA-purified extract was immunoprecipitated with a polyclonal anti-phosphotyrosine antibody a similar result was observed, except that no phosphorylation of the β -subunit was seen under basal conditions because in the intact cells the β -subunit does not contain phosphotyrosine before insulin stimulation (Fig. 1*c, d*)^{9,19}. During 1 h of incubation with insulin, the amount of ^{32}P -orthophosphate incorporated into the proteins eluted from the WGA-agarose was constant, suggesting that insulin stimulation of receptor phosphorylation does not result from a general increase in the specific activity of cellular ATP.

In an attempt to identify other phosphotyrosine-containing proteins, Fao cells were labelled and subjected to immunoprecipitation with anti-phosphotyrosine antibodies before WGA chromatography. In the absence of insulin, a single major phosphoprotein of M_r 120,000 was immunoprecipitated from the whole-cell extract (Fig. 1*e*). After incubation for 1 min with 100 nM insulin there was no change in pp120 (Fig. 1*f*), but we observed two new phosphoproteins of M_r 95,000 and 185,000 (Fig. 1*f*). pp95 is the β -subunit of the insulin receptor and was quantitatively immunoprecipitated by anti-insulin receptor serum (B2) (Fig. 1*g, h*). pp185, on the other hand was not recognized by this antibody, suggesting that it is a novel insulin-stimulated phosphotyrosine-containing protein that is antigenically distinct from the insulin receptor (Fig. 1*f, h*). The insulin dose-response curve for phosphorylation of pp185 was nearly identical to that for the β -subunit, supporting the notion that pp185 is a substrate for tyrosine phosphorylation by the insulin receptor kinase (Fig. 2).

The phosphoamino-acid composition of pp185, pp120 and the β -subunit of the insulin receptor was determined by partial acid hydrolysis and separation of the amino acids by high-voltage electrophoresis¹⁹. After insulin stimulation, each protein contained about equal amounts of phosphotyrosine and phosphoserine (Fig. 3); pp185 also contained substantial amounts

Fig. 3 Phosphoamino-acid analysis of pp185, pp120 and the β -subunit of the insulin receptor immunoprecipitated from whole-cell extracts with the anti-phosphotyrosine antibody. Fao cells were incubated in the absence (-) or presence (+) of insulin (100 nM) for 1 min. Phosphoproteins were immunoprecipitated from the whole-cell extracts with the anti-phosphotyrosine antibody and specifically eluted with *p*-nitrophenylphosphate, reduced with DTT and separated by SDS-PAGE. Dried gel fragments containing the β -subunit (a, b), pp185 (c, d) and pp120 (e, f) were incubated with trypsin ($50 \mu\text{g ml}^{-1}$) as described previously^{9,31}. The phosphoamino-acid composition of the eluted tryptic peptides was determined as described previously³¹. The phosphoamino-acid standards were visualized by reaction with ninhydrin and the radioactive amino acids were detected by autoradiography for 24 h.

of phosphothreonine. Although there was no distinct evidence of pp185 before insulin stimulation, there was a faint band that migrated slightly faster than pp185 which contained a small amount of phosphotyrosine (Figs 1e, 3c). Assuming that this is the same protein, insulin stimulated its phosphotyrosine content at least 10-fold (Fig. 3d). A significant increase in the amount of phosphoserine and phosphothreonine was also observed in pp185 after insulin stimulation, but whether this arises from *de novo* phosphorylation or tyrosine phosphorylation of previously phosphorylated pp185 is unknown. Before and after insulin stimulation, pp120 contained nearly equal amounts of phosphotyrosine, suggesting that it may be a substrate for an unidentified and constitutively activated tyrosine kinase in Fao cells.

Phosphorylation of the β -subunit is one of the earliest molecular responses that occurs in cells following insulin binding^{9,19}. As we have reported previously¹⁹, within 20 s after insulin stimulation (100 nM), phosphorylation of the β -subunit is maximal and remains at this elevated level for at least 1 h during uninterrupted exposure to insulin (Fig. 4). Phosphorylation of pp185 was also maximal by 30 s after exposure of the Fao cells to insulin, but it decreased during 60 min of continued insulin stimulation (Fig. 4); this decrease was not the result of a change in the specific activity of cellular [γ -³²P]ATP as there was no change in the level of phosphorylation of pp120 or of the β -subunit, which is rapidly dephosphorylated when the labelled ATP pool is diluted with a chase of unlabelled phosphate²⁰. Phosphoamino-acid analysis of pp185 indicated that concentrations of phosphoserine, phosphothreonine and phosphotyrosine decreased in parallel during this time interval (data not shown). These results suggest that following phosphorylation of pp185 there may be activation of a phosphoprotein phosphatase that recognizes pp185, but not the insulin receptor or pp120, as a substrate for dephosphorylation. These findings are consistent with the notion that the action of insulin may be regulated in the intact cell by both phosphorylation and dephosphorylation reactions²¹.

In the experiment shown in Fig. 4, phosphoproteins of M_r 75,000 and $>200,000$ were also detected by immunoprecipitation with the anti-phosphotyrosine antibody. The band of higher relative molecular mass showed similar kinetics to pp185,

Fig. 4 The time course of insulin-stimulated tyrosine phosphorylation. Fao cells were incubated in the absence (0 min) or presence of insulin for the indicated time intervals. Phosphoproteins were immunoprecipitated from the whole-cell extracts with the anti-phosphotyrosine antibody, eluted with *p*-nitrophenylphosphate and identified by SDS-PAGE and autoradiography as described in Fig. 1 legend.

whereas pp75 was present in the basal state and tended to increase after 30–60 min of insulin stimulation. These phosphoproteins were less abundant than the others described above and were observed only after prolonged exposure of the autoradiograms. Phosphoproteins with M_r s of 300,000–200,000 were detected by anti-phosphotyrosine antibodies in human fibroblasts stimulated with platelet-derived growth factor (PDGF)²².

Like the epidermal growth factor (EGF) receptor, PDGF receptor and several oncogene products, the insulin receptor is a tyrosine-specific protein kinase. Previous studies have successfully identified several cellular substrates (pp34, pp41, pp81, enolase, lactate dehydrogenase, phosphoglycerate mutase, vinculin) for the EGF receptor^{23–26}, PDGF receptor^{22,27} and pp60^{src} (refs 23, 24, 26, 28), but so far no endogenous substrates for the insulin receptor have been identified. The present study indicates that in addition to stimulating autophosphorylation of the insulin receptor, insulin stimulates tyrosine phosphorylation of a protein in intact hepatoma cells that has a M_r of 185,000. This protein (pp185) may have gone undetected by previous studies for several reasons. First, its rapid phosphorylation and dephosphorylation in insulin-stimulated cells mean that it can be detected only at early time points. Second, WGA chromatography is often used to purify cell extracts before studying insulin receptor phosphorylation²⁹, but as pp185 does not bind to this lectin it would not be detected in such experiments. Third, sodium vanadate, an inhibitor of dephosphorylation^{19,30}, was used in our studies during cell lysis and protein purification, but it has not been used routinely in the past. Finally, two-dimensional gel electrophoresis, which has been successful in identifying many tyrosine kinase substrates^{23,28}, may miss phosphoproteins with pI values <5.5 (ref. 27) or high- M_r phosphoproteins due to the background phosphorylation that occurs in this region²². These limitations can be avoided by using anti-phosphotyrosine antibodies, which provides specific probes for studying tyrosine phosphorylation events that occur during the initial response of cells to insulin.

Although the exact nature of pp185 is unknown, we can eliminate certain possibilities. pp185 does not bind to WGA and was not immunoprecipitated by the anti-insulin receptor serum B2, which recognized the mature receptor and the glycosylated and non-glycosylated (H. A. Hedo, personal communication) forms (M_r 155,000–190,000) of the precursor^{31,32}. Furthermore, the tryptic phosphopeptide map of pp185 does not correspond to the profile of β -subunit (data not shown). Thus, pp185 is not the insulin receptor. Fao cells show no specific EGF binding and no detectable tyrosine phosphorylation during EGF stimulation (data not shown), suggesting that pp185 is not related to

the EGF receptor (M_r 175,000). pp185 is also probably not the PDGF receptor (M_r 185,000) as the latter binds to WGA^{26,33}.

Immunoprecipitation of ³⁵S-methionine-labelled Fao cells by the anti-phosphotyrosine antibody did not reveal any band at M_r 185,000, although both the α - and β -subunits were easily detected (data not shown). Thus, pp185 is possibly a minor protein that is recognized with high affinity by the insulin receptor. Whether pp185 is directly phosphorylated by the insulin receptor kinase or is the result of activation of another tyrosine kinase in response to insulin is not yet known.

The only other prominent phosphoprotein in Fao cells that is recognized by the anti-phosphotyrosine antibody has a M_r of 120,000 and is constitutively phosphorylated on tyrosine residues. The nature of this phosphoprotein is unknown. Others have reported that ATP citrate lyase (M_r 116,000) is equally immunoprecipitated with a monoclonal antibody against phenylphosphonate before and after EGF stimulation of A431 cells because it contains phosphohistidine, which cross-reacts with this antibody²⁵; however, phosphoamino-acid analysis confirmed the presence of phosphotyrosine in pp120. Insulin stimulates tyrosine phosphorylation of a M_r -120,000 protein in a Triton X-100 extract of rat hepatocyte plasma membranes purified by WGA chromatography²⁹. It is unknown whether pp120 bears any similarity to the hepatocyte protein but they are probably different as pp120 identified here does not bind to WGA.

Our results provide the first demonstration, in an intact cell, of insulin-stimulated tyrosine phosphorylation of a protein other than the insulin receptor. Identification of pp185 should elucidate the relationship between the insulin receptor kinase and the mechanism of insulin action.

This work was supported in part by grants AM31036 and AM29770 to C.R.K. and a fellowship (AM0716301) to M.F.W. from the Institute of Health and Human Development, NIH, USPHS. We thank Drs D. T. Pang, B. R. Sharma and J. A. Shafer for the gift of phosphotyrosine binding antibody and for making available prior to publication the procedures for preparation of the antibody.

Aspirin causes short-lived inhibition of bradykinin-stimulated prostacyclin production in man

Dennis J. Heavey, Susan E. Barrow, Nicola E. Hickling & James M. Ritter

Department of Clinical Pharmacology, Royal Postgraduate Medical School, London W12 0HS, UK

Acetylsalicylic acid (aspirin) inhibits prostanoid synthesis^{1,2} by irreversible acetylation of fatty acid cyclooxygenase (EC 1.14.99.1)³. It thereby inhibits synthesis of pro-aggregatory thromboxane A₂ (TXA₂) by platelets^{2,4} and is widely used in the treatment and prophylaxis of vascular disease. Its efficacy, however, may be reduced since it also inhibits formation of prostacyclin (PGI₂)^{5,6} which is a vasodilator and anti-aggregatory agent^{7,8}. There is uncertainty over the optimum dose regimen for aspirin since although it inhibits platelet thromboxane production for many days⁴, the magnitude and duration of its effect on PGI₂ production by vascular endothelium *in vivo* is unknown. Resting plasma concentrations of PGI₂ (measured as the stable hydrolysis product 6-oxo-PGF_{1 α}) are at or below the limit of sensitivity of the most sensitive assays⁹ and cannot therefore be used to demonstrate a reduction in production. Bradykinin stimulates PGI₂ synthesis by cultured human vascular endothelial cells¹⁰ and we have shown that it stimulates PGI₂ production by man *in vivo*¹¹. We report here that an oral dose of aspirin (600 mg) causes rapid and substantial inhibition of bradykinin-stimulated PGI₂ production, but recovery occurs within 6 hours; this implies that endothelial PGI₂ synthesis would be spared most of the time during dosing once daily with even this relatively large dose of aspirin.

Seven healthy men aged 21-39 years, weight 68.5-85 kg, were studied. The protocol was approved by the Ethics Committee of the Royal Postgraduate Medical School, Hammersmith Hospital and subjects gave written informed consent. Bradykinin (RIA Biochemicals) was obtained as a solid, and a sterile, pyrogen-free solution in water was prepared, lyophilized and stored at -80°C. On the day of each study bradykinin was dissolved in sterile isotonic saline and passed through a 0.22- μ m filter (Millipore). PGI₂ production was stimulated by short intravenous infusions via an indwelling cannula in one forearm. Blood was sampled from a cannula in the other forearm. Bradykinin causes vasodilatation and swelling around the eyes and lips with a feeling of general discomfort, and the dose used, although the same within each subject, was varied from subject to subject depending on individual tolerance. The dose ranged from 0.15 to 0.8 μ g per kg body weight per min given as a single 5-min infusion or two consecutive 5-min infusions, the second at twice the dose of the first. The latter protocol improved tolerance in some subjects. During bradykinin infusions, blood pressure was recorded at 1-min intervals (Arteriosonde, Roche) and the electrocardiogram and skin temperature recorded continuously. Infusions were given before, and 30, 90, 180 and 360 min after drinking 600 mg soluble aspirin (Bayer) in 50 ml water. Blood samples (~20 ml) for measurement of the 6-oxo-PGF_{1 α} concentration were collected before and at the end of each bradykinin infusion. The ability of platelets to produce TXA₂ was determined by measurement of the stable hydrolysis product, TXB₂, in serum. Blood (2 ml) was taken immediately before each bradykinin infusion and incubated in a plain glass tube at 37°C for 1 h⁴. TXB₂ and 6-oxo-PGF_{1 α} were measured by a highly specific and sensitive method based on gas chromatography/negative-ion chemical ionization mass spectrometry (GC/NICIMS)^{9,12}.

Plasma concentrations of 6-oxo-PGF_{1 α} are shown in Table 1. Concentrations before bradykinin infusion were usually close to, or below, the limit of sensitivity of the assay (generally 1 pg ml⁻¹). In a few cases, especially in the control period, resting concentrations were higher, probably as a result of

Fig. 1 Effect of aspirin on serum TXB₂ concentration and bradykinin-stimulated PGI₂ production. Values shown are means \pm s.e. ($n=7$). Plasma 6-oxo-PGF_{1 α} concentrations are those measured at the end of each bradykinin infusion (Table 1). Blood (2 ml) taken immediately before each bradykinin infusion was allowed to clot in a plain glass tube at 37 °C for 1 h and serum TXB₂, the stable hydrolysis product of TXA₂, measured by GC/NICIMS. The serum TXB₂ concentration reflects the ability of platelets to synthesize TXA₂. In common with other investigators⁴, and in contrast to the effect on bradykinin-stimulated PGI₂ production, serum TXB₂ remained more than 99% inhibited 260 min after aspirin.

endothelial trauma during cannulation^{13,14}. In each subject the plasma 6-oxo-PGF_{1 α} concentration increased during the control bradykinin infusion (before aspirin), although 2 subjects (6 and 7) who tolerated only the lowest doses of bradykinin showed little stimulation. PGI₂ production was substantially inhibited 30 min after aspirin administration. In 5 of 7 subjects the stimulated 6-oxo-PGF_{1 α} concentration was below the detection limit. Assuming that the concentration in those cases was actually at the limit of detection, the mean inhibition of stimulated 6-oxo-PGF_{1 α} concentration was 86%. Recovery had usually occurred by 6 h. The serum TXB₂ concentration was inhibited by more than 99% at all times after aspirin. PGI₂ is a more potent vasodilator than bradykinin but even at 30 min after aspirin there was no attenuation of the vasodilator effects of bradykinin (data not shown). Figure 1 compares the effect of aspirin on TXA₂ and PGI₂ production. To rule out the possibility that the reduced PGI₂ synthesis at 30 min was a result of desensitization to bradykinin rather than inhibition by aspirin, three of the subjects were studied using the same protocol with placebo instead of aspirin. There was no effect on either serum TXA₂ generation or bradykinin-stimulated PGI₂ production (Fig. 2). The rapid recovery of PGI₂ after aspirin led us to believe that a dose of aspirin once daily would not cause a cumulative effect on bradykinin-stimulated PGI₂ synthesis and one subject was therefore given 600 mg daily for 7 days. On day 8, 18 h after

the last dose of aspirin, bradykinin infusion produced an increase in the plasma 6-oxo-PGF_{1 α} concentration which was again inhibited 30 min after a further dose of aspirin (600 mg) and recovered within hours (Fig. 3).

The tissue of origin of bradykinin-stimulated PGI₂ is likely to be vascular endothelium. Cultured human endothelial cells synthesize PGI₂ in response to bradykinin¹⁰, and we have found that during constant infusion of bradykinin the plasma concentration of 6-oxo-PGF_{1 α} rises to a plateau within 5 min (data not shown). Czervionke found that aspirin causes over 90% inhibition of PGI₂ production by cultured human endothelial cells, and recovery by synthesis of new cyclooxygenase is apparent within 2 h of washing¹⁵. Jaffe and Weksler obtained similar results with substantial recovery by 24 h¹⁶. The rate of recovery of cyclooxygenase activity *in vitro* after aspirin is highly dependent on culture conditions¹⁷, emphasizing the need for *in vivo* studies. Following an oral dose of 600 mg soluble aspirin, the peak plasma acetylsalicylic acid concentration occurs at 15 min, with very rapid elimination (elimination $t_{1/2}$ = 0.31 h)¹⁸. Tissues are therefore exposed to acetylsalicylic acid for only a short time. Our finding of a rapid inhibition of PGI₂ production with recovery in hours, although consistent with *in vitro* studies of endothelial cells, is seemingly at variance with the only previous *in vivo* study in man¹⁹, and with studies on human vascular tissue *ex vivo*²⁰⁻²². FitzGerald found that aspirin causes

Table 1 Effect of aspirin on bradykinin(BK)-stimulated production of 6-oxo-PGF_{1 α} (pg ml⁻¹)

Subject	Time after aspirin									
	Control		30		90		180		360	
	Pre	BK	Pre	BK	Pre	BK	Pre	BK	Pre	BK
1	1.7	12.9	<1	4.0	<1	17.1	<1	18.9	<1	26.9
2	1.1	10.2	2.2	<1	1.5	NA	<1	<1	<1	4.0
3	7.3	26.2	1.2	1.2	<1	<1	<1	3.6	<1	13.8
4	4.6	13.7	<1	<1.2	<1	1.1	<1	8.0	<1	22.0
5	<1	14.4	<1	<1	<1	<1	<1	13.0	<1	19.9
6	3.4	5.1	<1	<1	<1	<1	<1	<1	<1	8.3
7	<1	4.5	<1	<1	<1	<1	<1	<1	<1	3.3

PGI₂ production was stimulated by short intravenous infusions of bradykinin (BK). The dose of bradykinin was limited by its cardiovascular effects and adjusted for each subject on the basis of preliminary studies. Infusions were given before and at 30, 90, 180 and 360 min after a dose of soluble aspirin (600 mg in 50 ml water). Plasma concentrations of 6-oxo-PGF_{1 α} , stable hydrolysis product of PGI₂, were measured before and at the end of each bradykinin infusion by GC/NICIMS⁹. The limit of sensitivity of the assay is generally 1 pg ml⁻¹ for a 20 ml blood sample. Concentrations before bradykinin infusions were usually at or below the limit of detection. In each case there was an increase in the plasma 6-oxo-PGF_{1 α} concentration during the initial bradykinin infusion, although in subjects 6 and 7, who tolerated only the lowest doses of bradykinin, the rise was small. The increase in plasma 6-oxo-PGF_{1 α} concentration is inhibited 30 min after aspirin ($2\alpha = 0.02$, Wilcoxon's signed rank test) and recovery is seen over the following 360 min. NA, result not available.

Fig. 2 Effect of aspirin placebo on serum TXB₂ concentration and bradykinin-stimulated prostacyclin production in three subjects. There was no inhibition of bradykinin-stimulated prostacyclin production, showing that the inhibition seen following aspirin is not a result of desensitization caused by the short intervals between bradykinin infusions.

Fig. 3 Effect of chronic aspirin administration on bradykinin-stimulated PGI₂ production. One subject was studied twice. On one occasion he received 600 mg aspirin, having been drug-free for the previous 2 weeks (□), and on the second occasion he had taken aspirin 600 mg once daily for the previous 7 days, the last dose being 18 h before the dose taken on the study day (○). There was no cumulative effect of aspirin administered once daily on bradykinin-stimulated PGI₂ production, the time course of the effect being similar in the two studies. On day 8 of the chronic study, serum TXB₂ was >99% inhibited in the control (pre-aspirin) period compared with the same period of the acute study (data not shown).

only a partial (75%) inhibition of excretion of a urinary metabolite of PGI₂ even at doses of 2,600 mg daily, and recovery took more than 3 days¹⁹. The urinary metabolite, however, reflects production from many tissues with contributions from non-endothelial sources including vascular smooth muscle^{23,24}, pericardium²⁵, and gastric mucosa²⁶. If these tissues re-synthesize cyclooxygenase more slowly than does vascular endothelium, this could account for delayed recovery of the urinary PGI₂ metabolite following aspirin. If vascular endothelium contributes substantially to the urinary metabolite and recovers within hours of aspirin administration, then a 24-h urine collection will show only partial inhibition of excretion. Human vascular tissue removed 24–48 h after aspirin and incubated *ex vivo* still shows inhibition of PGI₂ production²². Much of the PGI₂ synthesized by such fragments, however, is derived from non-endothelial tissues²³, which may have a slower rate of re-synthesis of cyclooxygenase. Weksler has found that the endothelial surface of human saphenous veins has largely recovered PGI₂ synthesizing capacity by 24 h after a dose of

aspirin²⁷. Rapid endothelial cyclooxygenase synthesis could explain the finding that bovine aortic endothelial cyclooxygenase concentration is approximately 20-fold greater than that in the media²⁸.

Our results have therapeutic implications. There has been much effort expended in attempting to determine a dose of aspirin that is sufficiently low to cause selective inhibition of platelet TXA₂ synthesis without affecting PGI₂ production by vascular endothelium. The dose used in the present study is, by these standards, large. Our results indicate, however, that even this large dose has only a short-lived effect on endothelial PGI₂ production. More important than the use of a very low dose of aspirin is the need for a long dose interval, perhaps as long as several days²⁹ and certainly not less than 6 h.

Expression of N-myc in teratocarcinoma stem cells and mouse embryos

Aya Jakobovits*, Manfred Schwab†, J. Michael Bishop† & Gail R. Martin*

* Department of Anatomy, and † G. W. Hooper Foundation and Department of Microbiology and Immunology, University of California, School of Medicine, San Francisco, California 94143, USA

The N-myc gene, which is distantly related to the proto-oncogene c-myc, was first detected as an amplified sequence in human neuroblastoma cell lines and tumours^{1,2}. It has since been revealed that there is up to a 300-fold amplification of N-myc DNA in almost 50% of advanced metastatic human neuroblastomas, whereas amplification is not detected in less advanced tumours that have a better prognosis (ref. 3 and M.S., unpublished data). Although expression of N-myc is detectable in all neuroblastoma cell lines and tumours examined, its level is greatly enhanced when the N-myc gene is amplified^{4,5}. Recently, it has been shown that on co-transfection with the c-Ha-ras (EJ) gene, N-myc can induce

the malignant transformation of rat embryo fibroblasts⁶. Taken together, these data imply a function for *N-myc* in the development and/or progression of human neuroblastomas. Surveys indicate that *N-myc* also may be amplified and/or expressed in two other types of human tumours and cell lines derived from them: retinoblastomas and small cell lung cancers^{4,5,7,8}. Here, we report that *N-myc* is expressed at high levels in mouse and human teratocarcinoma stem cells, thus identifying another tumour cell type that expresses the *N-myc* gene. In addition, we found that *N-myc* is abundantly expressed in mouse embryos at mid-gestation and that its expression appears to decrease as the embryo approaches term. In the adult mouse, *N-myc* is expressed at an approximately fivefold lower level in the brain than in teratocarcinoma stem cells and embryos, and at even lower levels in the adult testis and kidney. Our data represent the first demonstration of expression of the *N-myc* gene in normal cells, and suggest that *N-myc* may be involved in mammalian embryogenesis.

Two mouse teratocarcinoma stem cell lines (embryonal carcinoma (EC) cells), PSA-1 (refs 9, 10) and F9 (ref. 11), were tested for the expression of *N-myc*. Both cell lines were isolated from embryo-derived teratocarcinomas and form tumours when injected subcutaneously (s.c.) into mice. The two cell lines are closely related to normal early embryonic cells¹² but differ in their ability to differentiate. Whereas PSA-1 cells are pluripotent and on differentiation both *in vivo* and *in vitro* give rise to a great variety of differentiated tissues, F9 cells have a very limited differentiative capacity. *N-myc* expression in PSA-1 and F9 cells was evaluated by Northern blot analysis of poly(A)⁺ cytoplasmic RNA isolated from the EC cells using a human genomic *N-myc* clone, pNb-1 (ref. 1). Both mouse EC cell lines were found to express a 3.2-kilobase (kb) *N-myc* transcript (Fig. 1). Although this transcript appeared to be relatively abundant as it was readily detected in 1 µg of total cytoplasmic RNA, it was at least 10-fold less abundant than the *N-myc* transcript of similar size observed in human neuroblastoma cells (Kelly line) in which the *N-myc* sequence is amplified ~100-fold¹ (data not shown). *N-myc* expression, equivalent to that found in PSA-1 cells, was also detected in poly(A)⁺ cytoplasmic RNA from cells of an embryonic stem cell (ESC) line (Fig. 1). Such ES cells, which are isolated from the fetal portion (inner cell mass, ICM) of a normal 4.5-day-old mouse embryo, are indistinguishable from tumour-derived teratocarcinoma stem cells and generally form teratocarcinomas with a wide variety of differentiated cell types when injected s.c. into mice^{13,14}. Thus, three tumorigenic cell lines which are known to have many properties in common with, or are directly derived from, the ICM of a normal mouse embryo, abundantly express *N-myc*. We also found that the cell line NTera2 clone D1 (ref. 15), derived from a human teratocarcinoma, abundantly expresses the 3.2-kb *N-myc* transcript (data not shown), whereas a mouse embryo fibroblast cell line, STO⁹, and a teratocarcinoma-derived endodermal cell line, PYS¹⁶, which is not tumorigenic, show no detectable *N-myc* expression (Fig. 1).

To determine whether this abundant expression in mouse EC and ES cells is due to *N-myc* gene amplification, we performed a Southern blot analysis of cellular genomic DNA (see Fig. 2). PSA-1, ES and F9 cells, in which *N-myc* is expressed at relatively high levels, appear to have the same number of copies of the gene as do mouse neuroblastoma cells, Neuro-2a, in which *N-myc* expression is very low and which have been shown to contain a single copy of *N-myc* per haploid genome⁴. Similarly, Southern blot analysis revealed equivalent numbers of *N-myc* copies in genomic DNA isolated from PSA-1, F9, ES and normal mouse spleen cells (data not shown). Therefore, the abundant expression of *N-myc* in EC and ES cells is not the consequence of gene amplification. Similarly, we found that the NTera2 clone D1 human teratocarcinoma cells, which also express relatively high levels of *N-myc* RNA, contain a single *N-myc* copy per haploid genome (data not shown).

In a recent study it was found that when human neuroblastoma cells are induced to differentiate *in vitro* they rapidly undergo a dramatic decrease in *N-myc* expression¹⁷. It seemed

Fig. 1 *N-myc* expression in mouse teratocarcinoma stem cells and their endodermal derivatives.

Methods. STO fibroblasts, F9 embryonal carcinoma cells and PYS endodermal cells were cultured as described previously (refs 9, 11 and 16, respectively). PSA-1 and ES cells (ESC), which are maintained in the undifferentiated state by co-culture with irradiated STO fibroblastic feeders, were cultured and separated from the feeder cells¹³. Endodermal derivatives of the F9 cells (F9-endo) were obtained by incubating cultures of undifferentiated cells with 2×10^{-7} M RA and 10^{-3} M db-cAMP for 4 days¹⁸. Endodermal derivatives of the PSA-1 cells (PSA-1-endo) were obtained by allowing the PSA-1 cells to form embryoid bodies¹⁰. After 6 days of culture in bacteriological dishes, the embryoid bodies were allowed to reattach to a collagen-coated tissue culture substratum; after 2 days, the endodermal cells were collected as described previously²³. Total cytoplasmic RNA was prepared from each of the cell types after lysis of the cell membranes with Nonidet P-40, followed by phenol/chloroform extraction¹⁷. Poly(A)⁺ RNA was isolated by affinity chromatography using oligo(dT)-cellulose and each lane was loaded with ~5 µg of denatured poly(A)⁺ RNA from the designated cell type. The RNAs were separated by electrophoresis in a 1% agarose-formaldehyde gel¹⁷, and the RNA species were transferred to nylon membrane (Gene Screen; NEN), crosslinked to the nylon membrane by ultraviolet irradiation and hybridized with either the nick-translated ³²P-labelled (4×10^8 c.p.m. µg⁻¹) 1-kb *Eco*RI-*Bam*HI fragment of pNb-1 human *N-myc* DNA¹ or chick β-actin DNA (ref. 24; provided by D. Cleveland), in 1 mM EDTA, 0.5 M NaHPO₄ pH 7.2, 7% SDS, and 1% bovine serum albumin (BSA)²⁵. The blot was washed in 1 mM EDTA, 40 mM NaHPO₄ pH 7.2, 1% BSA at 65 °C. The Gene Screen membranes were stripped of hybridized probe by washing in 70% formamide, 0.2×SSC, 0.1% SDS at 65 °C for 30 min. Autoradiographic exposure time, with an intensifying screen, was ~16 h for *N-myc* and 4 h for β-actin.

possible that mouse EC cells might show a similar regulation of *N-myc* expression during differentiation to endodermal cells as no *N-myc* expression was detectable in the established endodermal cell line, PYS (Fig. 1). Relatively pure populations of endodermal cells can be derived, by different methods, from the two EC cell lines studied. When PSA-1 cells are cultured as rounded aggregates, the outer cells spontaneously differentiate to endoderm. The two-layered structures that result, consisting of a solid core of undifferentiated cells surrounded by a single layer of endoderm, are known as simple embryoid bodies because of their similarity to the fetal portion of the normal 4.5-day-old mouse embryo^{9,10}. Purified populations of PSA-1-derived endodermal cells were obtained as described in Fig. 1 legend. F9 cells can be induced to differentiate to endoderm at high frequency in monolayer culture by treatment with retinoic acid (RA) and dibutyryl cyclic AMP (db-cAMP)¹⁸. Northern blot analysis of poly(A)⁺ cytoplasmic RNA from PSA-1-derived and F9-derived endodermal cells revealed readily detectable *N-myc* transcripts (Fig. 1). Densitometer tracings of the autoradiograms shown in Fig. 1 indicate that the ratio of *N-myc* RNA to β-actin RNA is approximately two to five times lower in F9-derived and PSA-1-derived endodermal cells than in their undifferentiated progenitors. If the levels of β-actin RNA are the same in EC and endodermal cells, these data suggest that

Fig. 2 Southern blot analysis of *N-myc* in genomic DNA from mouse cells. Genomic DNA was isolated from Neuro-2a mouse neuroblastoma cells⁴, PSA-1 and F9 embryonal carcinoma cells and ES cells, and 10 μ g of each was digested to completion with *Hind*III. The restriction fragments were separated on an agarose gel and transferred to nitrocellulose, then hybridized with nick-translated ³²P-labelled pNb-1 DNA as described previously¹.

the level of *N-myc* RNA decreases as EC cells differentiate to endoderm.

It is not clear why the 'primary' endodermal cells express readily detectable levels of *N-myc* RNA whereas PYS cells express little or none. It is possible that the *N-myc* expression observed in the endodermal cultures reflects the presence of a subpopulation of undifferentiated cells. However, by morphological criteria the culture of PSA-1-derived cells was almost exclusively of an endodermal phenotype. In addition, when the Northern blot of the RNAs from F9 and F9-endo cells shown in Fig. 1 was rehybridized with a probe for the *c-myc* gene, it was apparent that whereas relatively high levels of *c-myc* RNA are expressed in undifferentiated F9 cells, this RNA is barely detectable in their endodermal derivatives (data not shown). These results, which are in agreement with data from previous studies of *c-myc* expression in F9 cells and their endodermal derivatives¹⁹, suggest that there are relatively few undifferentiated cells in the endodermal populations. Another possible explanation for the differences in *N-myc* expression in primary as compared with PYS endodermal cells is that *N-myc* RNA has a relatively long half-life and that the *N-myc* RNA detected in primary endodermal cells was transcribed before differentiation. Alternatively, it is possible that the primary endodermal cultures contain cells in a state of differentiation which differs from that of PYS cells.

The results of this study raise the question of the functional significance of the abundant *N-myc* gene expression in teratocarcinoma cells. It is conceivable that the relatively high levels of *N-myc* expression in EC cells are a function of their tumorigenicity; alternatively, abundant *N-myc* expression may be a characteristic of early embryonic cells and therefore the *N-myc* expression observed in embryonal carcinoma and embryonic stem cells might be one manifestation of their close similarity to normal early embryonic cells. Although we have not tested this hypothesis directly as it is not feasible to obtain sufficient RNA for Northern blot analysis from the ICM cells to which EC and embryonic stem cells correspond, we have studied *N-myc* expression in embryos at later stages of development. Figure 3 shows the results of Northern blot analysis of *N-myc* expression in embryos collected at daily intervals from 9.5 to 17.5 days of gestation. At each stage the embryo proper was separated from the extraembryonic membranes and placenta, an appropriate number of embryos were pooled, and total cellular poly(A)⁺ RNA was isolated. In addition, total cellular

Fig. 3 *N-myc* expression in mouse embryos at various stages of gestation. *a*, Total cellular RNA isolated from embryos at 7.5 and 9.5 days of gestation and hybridized with an *N-myc* probe. The lanes contain ~5 or 10 μ g of RNA, as indicated. *b*, Poly(A)⁺ cellular RNA isolated from embryos at days 9.5–17.5 of gestation, hybridized with *N-myc* probe. Each lane contains ~5 μ g of RNA. *c*, The blot shown in *b* was stripped of probe as described in Fig. 1 legend and hybridized with a subclone of exon 3 of the human *c-myc* oncogene (*Cla*I/*Eco*RI fragment; provided by N. Hay). **Methods.** Embryos were obtained by mating mice of various inbred genotypes. The day on which the genital plug was detected was designated as day 0.5 of gestation. At each stage, total RNA was immediately extracted from a pool of embryos following homogenization in guanidine thiocyanate²⁶. RNA was isolated and analysed as described in Fig. 1 legend.

Fig. 4 *N-myc* expression in adult mouse organs. Approximately 4 μ g of poly(A)⁺ RNA from PSA-1 teratocarcinoma stem cells (EC) and from embryos at day 11.5 of gestation, and ~10 μ g of poly(A)⁺ RNA isolated from organs obtained from randomly bred adult mice, were analysed as described in Fig. 1 legend.

RNA was isolated from a pool of embryos at 7.5 days of gestation. The results of this experiment show that *N-myc* RNA was detectable at all stages tested. Figure 3*a* shows that *N-myc* RNA is detectable in 5 μ g of total RNA from embryos at 7.5 and 9.5 days of gestation, indicating that *N-myc* expression is relatively abundant at these stages of development. The level of expression in these embryos is roughly equivalent to that in PSA-1 cells (data not shown). Figure 3*b* shows the level of *N-myc* expression in poly(A)⁺ RNA isolated from embryos at days 9.5–17.5 of gestation. Roughly equal amounts of RNA were loaded in each lane, and this equivalence was confirmed by

rehybridization of the blot with a cloned probe for β -actin (data not shown). From these results it seems that the level of N-myc RNA is highest at days 7.5–11.5 of development and thereafter decreases with increasing time of gestation. The Northern blot shown in Fig. 3b was also rehybridized with a probe for the c-myc gene (Fig. 3c); in contrast to the differential expression observed for N-myc, the levels of c-myc RNA did not change with increasing stage of gestation. The latter results are largely consistent with previous studies²⁰. These data, taken together with the results of studies of the expression of various other oncogenes in mouse embryos^{20–22}, indicate that N-myc, c-myc and other oncogenes are regulated independently during development.

We also tested various organs from adult mice for expression of N-myc. N-myc RNA was readily detected in poly(A)⁺ RNA isolated from brain, was less abundant in RNA from testis and kidney (Fig. 4), but was not detectable in RNA from spleen or liver (data not shown). Densitometer tracings of the autoradiograms indicated that the ratio of N-myc to β -actin RNA is approximately fivefold higher in teratocarcinoma stem cells and in embryos at the mid-gestation stages of development than in brain.

The data presented here demonstrate that the N-myc gene is expressed during normal mouse embryogenesis and in certain organs of the adult. From the results of our study of teratocarcinoma cells, and assuming that these cells provide a valid model system for the study of gene expression in the peri-implantation mouse embryo, it seems likely that N-myc is expressed at relatively high levels by ICM cells at around the time of implantation. In contrast, primary endoderm, which is the first differentiated cell type formed by the ICM, may express it at a lower level. We have demonstrated directly that abundant N-myc expression is characteristic of the mid-gestation embryo and that the level of expression decreases at later stages of embryogenesis. An intriguing possibility is that the abundant N-myc RNA detected in embryos at earlier stages of development is a manifestation of N-myc expression in most or all cells of the embryo, whereas the decreased levels of N-myc RNA at later stages reflect expression in a very limited number of cell types, possibly only in those tissues in which N-myc is expressed in the adult (for example, brain, testis and kidney). The results of *in situ* hybridization studies of embryos and adult organs, now in progress, will help to elucidate the tissue and cell specificity of N-myc expression. The information from such studies should ultimately contribute to our understanding of the normal function of the gene.

This work was supported in part by grants from the American Cancer Society to G.R.M. and from the National Cancer Institute (NIH) to J.M.B., and by funds from the G.W. Hooper Foundation. A.J. is a recipient of a senior postdoctoral fellowship from the California Division of the American Cancer Society. We thank Dr Alexandra Joyner for providing the poly(A)⁺ embryo RNA, Drs Joyner and George Church for technical advice and helpful discussion, and Ms Joy Graesser for technical assistance.

The enzyme isopenicillin N synthetase (IPS) catalyses the oxidative condensation of δ -(L- α -aminoadipyl)-L-cysteinyl-D-valine (LLD-ACV) to isopenicillin N, which is a central reaction in the pathway to clinically important penicillins and cephalosporins. Here we report the cloning, characterization and expression in *Escherichia coli* of the gene encoding the IPS protein in *Cephalosporium acremonium*. The IPS gene was identified by purifying IPS protein, determining the first 23 amino-terminal amino acids, preparing a set of synthetic oligonucleotides encoding a portion of the determined amino-acid sequence, and probing a cosmid genome library with the mixed oligonucleotides. A cosmid hybridizing with the probe was isolated and the IPS gene was localized and sequenced. The IPS gene encodes a polypeptide of relative molecular mass (*M*_r) 38,416. When this open reading frame was cloned into an *E. coli* expression vector and inserted into *E. coli*, the recombinant *E. coli* produced a new protein co-migrating with authentic IPS as the major protein of the cell (~20% of cell protein). Crude cell extracts condensed LLD-ACV to a penicillinase-sensitive molecule whose antibacterial activity indicated that it was isopenicillin N.

The conversion of LLD-ACV to isopenicillin N by IPS or cyclase is carried out by a variety of organisms, including *Penicillium chrysogenum*, *C. acremonium*, *Streptomyces clavuligerus* and other Actinomycetes. Penicillins and cephalosporins are isolated from these organisms for the manufacture of important β -lactam antibiotics. The cyclase enzyme, in the presence of Fe²⁺ and ascorbate, removes four hydrogens from LLD-ACV and consumes one oxygen, resulting in the formation of the two rings found in isopenicillin N¹. Most of the studies of the IPS reaction have examined enzymes from *C. acremonium* and *S. clavuligerus*. The *C. acremonium* enzyme has been purified^{2,3}, and used to condense not only LLD-ACV to isopenicillin N, but also variants of LLD-ACV to different β -lactam structures^{4–7}. In order to extend our knowledge of the properties and potential of the IPS enzyme, we have cloned the IPS gene and expressed the activity in *E. coli*.

IPS protein from *C. acremonium* was purified using modified published procedures² with additional reverse-phase HPLC steps. The purified protein was then subjected to amino-terminal sequence analysis, and 23 amino-acid residues were determined (see Fig. 1). Sixty-four synthetic oligonucleotides were prepared, one of which must be the perfect match of the coding information

§ To whom correspondence should be addressed.

Fig. 1 Amino-terminal sequence analysis of IPS and synthesis of oligomeric DNA probes. **A**, The first 23 amino-terminal amino-acid residues of IPS. The question mark indicates that the first cycle of the sequenator run was ambiguous. The underlined sequence (residues 18–23) represents the region encoded by the synthetic oligonucleotides. **B**, The possible RNA codons for the underlined sequence in **A**. As the third position of each codon is variable in this region, all possibilities are shown. **C**, Two sets of 17-mer oligonucleotides incorporating the possibilities shown in **B** were synthesized. Each pool has a complexity of 32. **D**, The experimentally derived DNA sequence and the corresponding predicted amino-acid sequence (see Fig. 3).

Methods. Extraction and purification of IPS from *C. acremonium* were done as described by Pang *et al.*² except that the Dyno-Mill agitator disks were run at 2,000 r.p.m. to keep the temperature below 5°C during disintegration of the mycelium. The peak fractions containing the synthetase were used for further processing. Nearly pure IPS protein was applied to a ProRPC HR 5/10 C₈ reverse-phase column using a Pharmacia FPLC system. The A solvent was 0.1% trifluoroacetic acid and 0.1% morpholine in water; the B solvent was 80% isopropanol, 20% acetonitrile with 0.1 ml per 100 ml each of trifluoroacetic acid and morpholine. The column was run at 0.3 ml min⁻¹ with a series of the following linear gradients: from 0 to 5 ml of elution buffer, B went from 0 to 30%; from 5 to 23 ml B went from 30 to 70%; and from 23 to 25 ml B went from 70 to 100%. The 64 deoxyoligonucleotides were chemically synthesized in two pools of 32 17-mers each, using an Applied Biosystem DNA Synthesizer (Model 380-A) according to the manufacturer's recommended protocols. Oligomers were purified by 20% polyacrylamide/7 M urea gel electrophoresis.

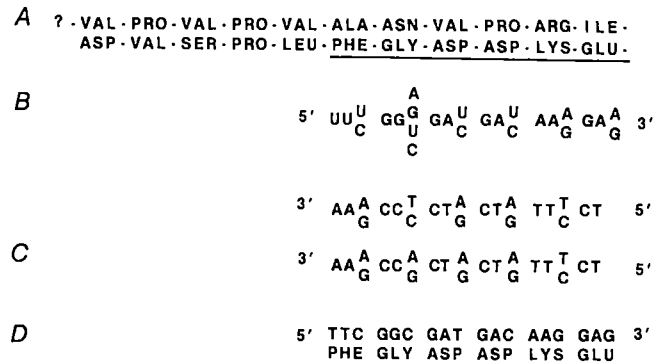

Fig. 2 Schematic diagrams of cosmids and plasmids used in the present study. The size of the circle is not proportional to the size of the plasmid. Except where indicated below, if a restriction enzyme cut site is indicated on the drawing, all restriction sites for that enzyme are included in the diagram. pKC462*, a 12.4-kb cosmid constructed by R. N. Rao and R. Stanzak (personal communication) which contains a *Streptomyces* origin of replication (Str Ori) from pFJ103 (ref. 10), and an *E. coli* origin of replication (ori) from pBR322. Antibiotic resistance markers on this plasmid are the ampicillin resistance gene (ApR) from pBR322, the apramycin resistance gene (AmR) from pKC222 (ref. 11), and the neomycin resistance gene (NmR) from Tn5. The three *cos* sites (*cos*) are from bacteriophage λ . pKC462* contains a unique *Bam*HI restriction site (used in this study for cloning) flanked by unique *Eco*RI restriction sites. pIT328, an ~50-kb plasmid created by ligating *C. acremonium* genomic DNA partially cleaved with restriction enzyme *Mbo*I into the *Bam*HI site of pKC462*. pIT328 contains ~40 kb of *C. acremonium* DNA (Ceph. insert). The cross-hatched box indicates the protein-coding region of the IPS gene. *Hind*III* is one of at least 10 *Hind*III sites in the insert, the rest of which are not shown. pIT335, an 8.2-kb plasmid, was constructed by digesting pIT328 with *Hind*III and re-ligating, thus eliminating half the vector and all but ~4.5 kb of the *Cephalosporium* DNA insert. The IPS gene is transcribed in the direction of the arrow. Only the relevant restriction sites are shown, and one more unmapped *Nco*I restriction site exists outside the IPS gene in pIT335. pIT336, a 4.1-kb plasmid, was created by cloning a 1,400-bp *Eco*RI-*Xho*I fragment from pIT335 into the *Eco*RI-*Sal*I sites of pUC8 (ref. 12). The *Cephalosporium* DNA insert (IPS) contains most of the protein-coding region of the IPS gene. pIT337 is an 11.6-kb expression plasmid containing the complete coding region of the IPS gene. The 1,460-bp *Nco*I-*Bam*HI fragment from pIT335 was ligated with two fragments (an 8.7-kb *Nco*I-*Nco*I fragment and a 1.5-kb *Nco*I-*Bam*HI fragment) from pCZ106. pCZ106 is a derivative of pCZ115 (ref. 13) which contains the bovine growth hormone gene transcribed from the *E. coli* tryptophan promoter and a temperature-sensitive copy control (runaway replicon) system. The *E. coli* tryptophan promoter (*trp* pro) drives transcription of the IPS gene. The location and direction of transcription of the IPS gene and of the neomycin resistance gene (*NmR*) are also indicated.

Methods. *C. acremonium* genomic DNA was isolated from protoplasts prepared according to Queener *et al.*¹⁴. The protoplasts were lysed by incubating them in 3% *N*-lauroyl sarkosyl, 0.5 M Tris-HCl pH 9.0, 0.2 M EDTA at 65°C for 15 min. The mixture was cooled and then extracted with buffered phenol (10 min) and chloroform (10 min). The DNA layer was mixed with a 1:10 volume of 5 M KOAc and spooled with 2 vol. of cold 100% ethanol. DNA was dissolved in 2 ml TE buffer (10 mM Tris-HCl pH 7.5, 0.1 mM EDTA) then treated with 50 μ g ml⁻¹ proteinase K (Sigma; Type XI) at 65°C for 1 h in 0.01 M Tris-HCl pH 7.8, 5 mM EDTA, 0.5% SDS. The solution was then extracted for 10 min each with buffered phenol and chloroform and the DNA respoiled and suspended in 0.5 ml TE buffer. Partial enzymatic digestions with *Mbo*I were done to achieve an average size of 30–40 kb. pKC462* was digested with *Hpa*I, treated with alkaline phosphatase, then cut with *Bam*HI. The partially digested genomic DNA was ligated into the *Bam*HI site of pKC462* and the recombinant DNA molecules were packaged into phage λ heads using Promega Biotec packaging extracts according to the recommendations of the manufacturer. *E. coli* SF8 cells grown in the presence of 0.2% maltose were transduced with the recombinant λ particles and cells containing cosmids were selected on plates containing 100 μ g ml⁻¹ ampicillin and then grown in liquid culture in microtitre dishes in the presence of 100 μ g ml⁻¹ apramycin. The library was screened according to the method of Grunstein and Hogness¹⁵. Oligonucleotide probes (described in Fig. 1 legend) were kinased under conditions described previously¹⁶. The nitrocellulose filters containing the recombinant *E. coli* were hybridized at 42°C for 2 h in 10 \times Denhardt's, 6 \times SSC, 0.1% sodium pyrophosphate¹⁷. Washes were at room temperature in 6 \times SSC for 30 min, followed by another 5-min wash in 6 \times SSC at 42–58°C.

Fig. 3 A, Complete nucleotide and predicted amino-acid sequence of isopenicillin N synthetase gene from pIT335. The DNA sequence was determined by the chemical method of Maxam and Gilbert⁸ as described previously¹⁶. Both strands were sequenced for over 95% of the protein-coding region, and the remaining areas were sequenced at least twice from different sites on the same strand. The primary sequence of the IPS gene, together with 118 bp preceding the initiation codon and 455 bp after the termination codon, is shown with the predicted amino-acid sequence of a 1,017-bp open reading frame. Numbers above the nucleotide sequence refer to base-pair location. Amino-acid residues are numbered below the protein sequence. The proposed translation initiation site is amino-acid 1. B, Analysis of G+C content as a function of position in the codon. Each curve represents the G+C content of one of the three codon positions. The per cent G+C at each base is calculated as a forward average of 20 codons according to the algorithm of Bibb *et al.*⁹. For clarity, the curves presented are smoothed slightly relative to the original computer print-out. The heavy line corresponds to the first base of a codon, the dotted line refers to the second base, and the thin line refers to the third position. The arrows along the axis indicate the limits of the IPS protein-coding region (see A).

for amino acids 18–23 (Phe-Gly-Asp-Asp-Lys-Glu) encoded by the IPS gene. The 64 possible 17-mer oligonucleotides were synthesized in two pools of 32 (Fig. 1). The pool of 32 that hybridized most efficiently to restriction enzyme-cleaved *C. acremonium* genomic DNA immobilized on nitrocellulose was used for further experiments.

The synthetic 17-mer oligonucleotides were used to screen a cosmid genome bank for the IPS gene. The region of one cosmid, pIT328, which hybridized to the oligonucleotide probes was determined to be adjacent to the *E. coli* selectable markers by restriction mapping and Southern hybridizations, so the cosmid was truncated by restriction enzyme *HindIII* digestion and re-ligation to yield the 11-kilobase (kb) plasmid pIT335 (Fig. 2). The DNA sequence of a portion of pIT335 was determined by the Maxam-Gilbert technique⁸ and the predicted amino-acid sequence of one region matched the experimentally determined amino-acid sequence of the IPS protein (Fig. 3). The open reading frame containing this information (Fig. 3) can encode a polypeptide of M_r 38,416. The reported M_r of the IPS protein, as determined by SDS-polyacrylamide gel electrophoresis, is 40,000 (ref. 3) (see also Fig. 4).

The predicted amino-acid sequence of the IPS protein from pIT337 (Fig. 3) begins with methionine and glycine residues which are not found in the protein isolated from *Cephalosporium* cells. These residues are evidently cleaved post-translationally in *Cephalosporium*.

The protein-coding region of the IPS gene consisted of 63% G-C base pairs. Because of the high G+C content, we used an algorithm described by Bibb *et al.*⁹ to examine the G+C content of the DNA sequence as a function of position in the triplet codons. Bibb *et al.* have shown that the G+C content of the

positions in the triplet codons is biased within protein-coding regions but relatively random outside protein-coding regions for organisms with DNA of high G+C content. In particular, Bibb *et al.* found that the G+C content of the first position in the codon was about average, while that of the second position was much lower, and that of the third position much higher than average. As shown in Fig. 3, the same pattern of G+C content bias was observed for the open reading frame encoding the IPS protein. This provides further evidence that the open reading frame identified by sequencing is correct for its entire length, since a shift in reading frame would have also shifted the G+C content bias.

To further prove that the open reading frame encodes the IPS protein, we fused the open reading frame to an *E. coli* expression system. The open reading frame from pIT335 was isolated on an *NcoI*-*BamHI* fragment. The recognition sequence for the restriction enzyme *NcoI*, 5'-CCATGG, surrounds the methionine codon that initiates translation of the open reading frame (Fig. 3). The restriction enzyme *BamHI* cleaves ~450 base pairs (bp) downstream from the proposed translation termination site. The *NcoI*-*BamHI* fragment was ligated into an *E. coli* expression vector to create pIT337. The *E. coli* expression vector used the promoter and ribosome binding site from the *E. coli* tryptophan operon and a temperature-sensitive copy control system ('runaway replicon'). *E. coli* cells transformed with pIT337 produce a new protein which co-migrates with authentic IPS protein on SDS-polyacrylamide gels. At low temperatures the cells produce low amounts of the new protein, but at high temperatures they produce about 20% of total cell protein as the putative IPS polypeptide (Fig. 4). The other new major protein band produced by the transformed *E. coli* cells is

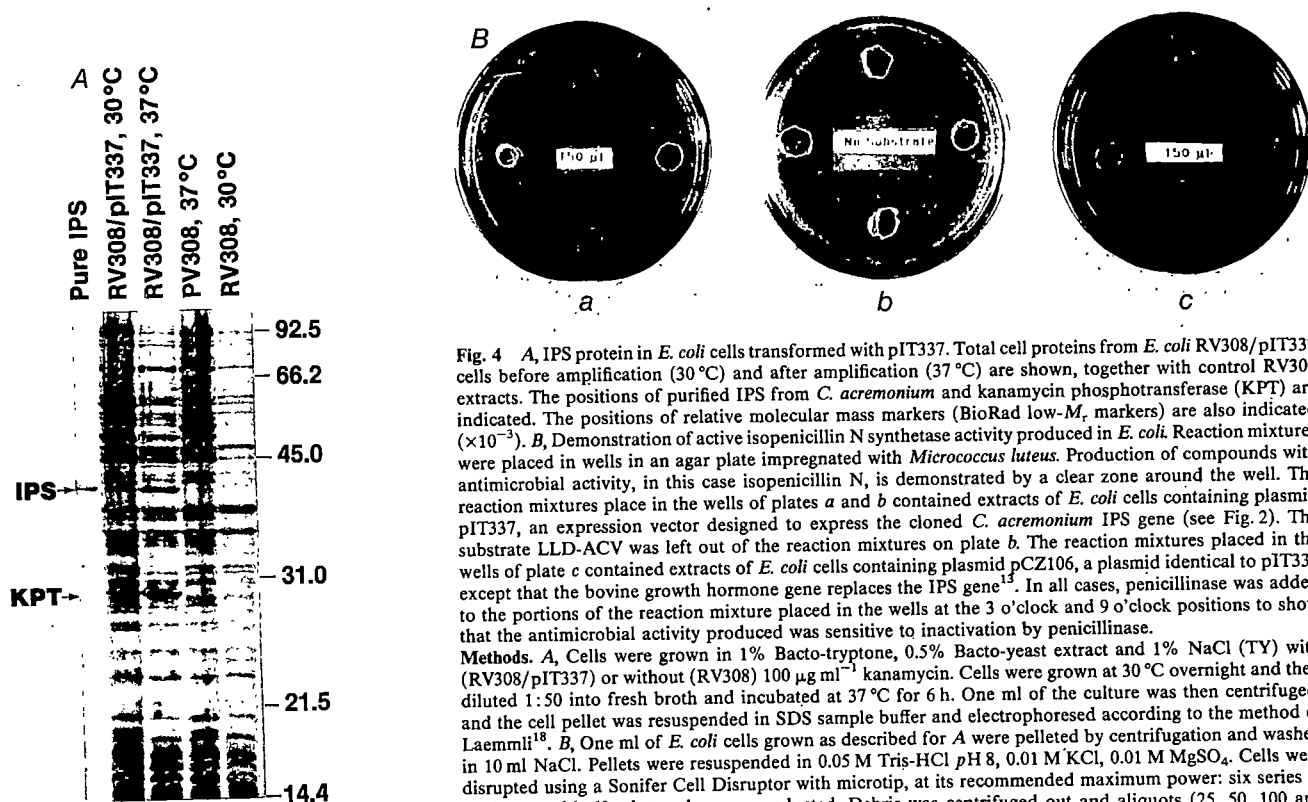

Fig. 4 A, IPS protein in *E. coli* cells transformed with pIT337. Total cell proteins from *E. coli* RV308/pIT337 cells before amplification (30 °C) and after amplification (37 °C) are shown, together with control RV308 extracts. The positions of purified IPS from *C. acremonium* and kanamycin phosphotransferase (KPT) are indicated. The positions of relative molecular mass markers (BioRad low-M_r markers) are also indicated ($\times 10^{-3}$). B, Demonstration of active isopenicillin N synthetase activity produced in *E. coli*. Reaction mixtures were placed in wells in an agar plate impregnated with *Micrococcus luteus*. Production of compounds with antimicrobial activity, in this case isopenicillin N, is demonstrated by a clear zone around the well. The reaction mixtures placed in the wells of plates a and b contained extracts of *E. coli* cells containing plasmid pIT337, an expression vector designed to express the cloned *C. acremonium* IPS gene (see Fig. 2). The substrate LLD-ACV was left out of the reaction mixtures on plate b. The reaction mixtures placed in the wells of plate c contained extracts of *E. coli* cells containing plasmid pCZ106, a plasmid identical to pIT337 except that the bovine growth hormone gene replaces the IPS gene¹³. In all cases, penicillinase was added to the portions of the reaction mixture placed in the wells at the 3 o'clock and 9 o'clock positions to show that the antimicrobial activity produced was sensitive to inactivation by penicillinase.

Methods. A, Cells were grown in 1% Bacto-tryptone, 0.5% Bacto-yeast extract and 1% NaCl (TY) with (RV308/pIT337) or without (RV308) 100 $\mu\text{g ml}^{-1}$ kanamycin. Cells were grown at 30 °C overnight and then diluted 1:50 into fresh broth and incubated at 37 °C for 6 h. One ml of the culture was then centrifuged, and the cell pellet was resuspended in SDS sample buffer and electrophoresed according to the method of Laemmli¹⁸. B, One ml of *E. coli* cells grown as described for A were pelleted by centrifugation and washed in 10 ml NaCl. Pellets were resuspended in 0.05 M Tris-HCl pH 8, 0.01 M KCl, 0.01 M MgSO₄. Cells were disrupted using a Sonifier Cell Disruptor with microtip, at its recommended maximum power: six series of 5-s bursts with 60-s intervals were conducted. Debris was centrifuged out and aliquots (25, 50, 100 and 150 μl) were assayed for isopenicillin N synthetase activity according to Shen *et al.*¹⁹.

kanamycin phosphotransferase, which is also encoded on the *E. coli* expression vector.

Crude cell-free extracts from cells containing pIT337 also contain IPS activity. Extracts were incubated with LLD-ACV and the reaction mixture tested for antimicrobial activity on agar plates impregnated with *Micrococcus luteus*. As shown in Fig. 4, generation of antimicrobial activity in the assay was dependent on the presence of the IPS gene in the *E. coli* expression vector and on exogenous addition of LLD-ACV. These results indicate that the open reading frame from pIT335 encodes a polypeptide with IPS activity, and that the polypeptide is expressed in an active form in *E. coli*.

The cloning and expression of the IPS gene from *C. acremonium* will facilitate further analysis of the penicillin-cephalosporin biosynthetic pathway. The enzymatic properties and structure/function relationships of IPS can now be tested

in more detail because of the greater availability of the synthetase. The properties of the *Cephalosporium* gene, especially with respect to the control of transcription, can also be studied. Control of expression of the IPS gene is particularly interesting because β -lactam antibiotics are usually produced late in the growth cycle, suggesting the possibility of control of expression of the biosynthetic genes themselves. These aspects are presently under investigation.

We thank the Lilly Research Laboratories (a division of Eli Lilly & Co.) for financial support and the following individuals for encouragement: R. H. Baltz, J. P. Burnett, N. Neuss, E. Flynn, J. Whitney, R. Losick and D. Dennen. We also thank R. N. Rao for providing pKC462⁺; B. Weigel, R. Stanzak, G. Wiseman, S. Burgett, J. Shrote, C. Beckage and G. Griesinger for advice and assistance; and R. H. Baltz for a critical review of the manuscript.

Impaled on Morton's fork

British archaeologists, bent on organizing a successful international conference next year, should have found a more honourable way out of their problem over South African apartheid.

By the time this issue of *Nature* reaches its readers, the British National Committee of the International Union of Prehistoric and Protohistoric Sciences (IUPPS) will have made the most difficult decision ever to have come its way. For the best part of a year, the committee has been planning the 11th World Archaeological Congress, arranged for Southampton next September (see *Nature* 31 October, p.754). Just two months ago the organizers found themselves in what they judged to be an impossible position. Local interests at Southampton had complained that they would boycott or even disrupt the congress if scientists from South Africa were allowed to attend. The committee seems to have spent the summer agonizing about the problem, and the obvious conflict there would be between a decision to give in to opponents of the conference and the ringing declaration of the parent body, IUPPS, there should be no discrimination in its proceedings on the grounds of "nationality, philosophical conviction or religious faith". The issue was further complicated by the circumstance that the chairman of the British organizing committee, Professor John Evans, is also president of IUPPS. But in the end, the organizers decided that they had better bow to pressure to disinvite South Africans. A note to that effect was included in the final version of the conference programme.

This week's meeting (on 20 November) has the unavoidable purpose of mulling over the damage that has been done to international scholarship, to the reputation of British academic institutions and, more practically, to the chances that the planned congress will be a success, financially as well as intellectually. There are three choices: to stand by the decisions already made, to go back on them (letting the opposition go hang) or to cancel the congress (perhaps in the hope that it might be possible to hold it elsewhere at some other time). It probably matters very little what the committee decides. Most of the damage has already been done.

The rights and wrongs of the underlying issue are widely understood. The South African system of apartheid, one of the few systems of racial discrimination enshrined in a nation's constitution, is wicked, and should be done away with. Most people agree with that. In the past few years, external pressure has helped to moderate the South African government's policies, and there is now a chance that further pressure will make the system of apartheid untenable. That proposition (or package of propositions) is less unanimously accepted. Plain speaking certainly helps. Economic sanctions have dubious direct effect, but may have symbolic value. The steps taken by the governments of the British Commonwealth under the Gleneagles agreement to make it difficult for sportsmen who play games in South Africa then to play the same games for their own representative teams have been an endless source of trouble but are probably nevertheless worthwhile, given South Africa's fondness for most kinds of games. But the pressures to which the organizers of the Southampton congress have been subjected appear to derive from the belief that if South African scientists are denied the chance to play a part in international conferences, their government will similarly cave in. To say the least of it, that proposition is untested.

Whatever the chances, there seems no doubt that IUPPS and its British organizing committee should have resisted the pressures

to which it was itself exposed during the summer. IUPPS is not, after all, the government of South Africa. Its constitution does include the stirring declaration that its proceedings are open to all. The British committee's two public statements of its reasons for disinviting South Africans, on 19 September and 22 October, refer to the decision as "hard" and as "taken under duress"; the second "keenly regrets the breach of the principle of free academic interchange". The first refers to the "pressure from several official and worthy organizations" in Britain "which maintain a policy of a total academic boycott of South Africa". The second more explicitly explains that if some of the proposed sponsors of next year's congress, the Southampton City Council in particular, were to withdraw support, the organizing committee might lose as much as £100,000, a quarter of the congress budget. Plainly one reason why the decision was so hard to make was that the committee members were forced to swallow their pride for lack of financial independence.

Nobody should take advantage of the committee's plight to throw brickbats at it. There is no reason to suppose that its members share the views of the pressure groups complaining that South Africans might attend the congress, and which have threatened trouble if they do. But it is fair to ask why the committee, conscious as it appears to have been of the principles of academic freedom, should have caved in so quickly and privately. At the least, it might have made a public issue of its dilemma, pleading the aid of other academic organizations or of academic opinion in general. The committee may have thought it had a duty, in the summer, to act quickly so as to make its conference a success, but by what right did it assume the responsibility of electing itself to be the first academic body to promulgate discriminatory regulations against fellow academics?

For the academic community as a whole, the objective now should be to forfend against future trouble of the kind that has afflicted the British offshoot of IUPPS. The Southampton City Council, the largest single sponsor of the planned conference, seem to have influentially twisted the organizers' arms: the lesson is that academics should not accept support if there are, or may be, strings attached. Student organizations seems to have been influential at Southampton in threatening to deny accommodation to visitors if South African scholars were among them, but it is far from clear how students to whom universities rent accommodation during term-time can decide what happens to it during the vacations, when they pay no rent. But particular responsibility for the IUPPS dilemma, and perhaps even for the collapse of a worthwhile conference, attaches to the Association of University Teachers, which has pursued a policy of "academic boycott" in relation to South Africa; is that what British academics wish their representative body to be saying?

To resist these pressures would of course be inconvenient. Congresses would be less grand if city councils were less generous, and would be less well attended if there were not cheapish student accommodation in which people could stay. There is also a danger that scientists from other countries would stay away if South Africans were free to attend, impeding the process of scientific communication. But scientific organizations are not powerless in the face of such difficulties. Plain speaking, and persuasion in the interests of tolerance, are freely at their disposal. They are tools too little used. □

US science budget

Congress sets upper limits for federal agencies

Washington

THE US Congress has not done as badly by research this year as many had feared it would. In spite of the strong political pressures to be seen doing something to reduce the federal budget deficit, attempts to freeze some appropriations at 1985 levels were defeated. But Congress conspicuously failed to meet the administration's budget requests for several agencies in the new financial year. The National Science Foundation (NSF) and the National Aeronautics and Space Administration (NASA) are among the casualties.

NASA's budget for research and development in the year which began on 1 October is fixed at \$2,757 million, the figure that had been urged by the House of Representatives; the Senate had wanted an extra \$20 million. The sum now agreed represents an increase of \$335 million over last year's figure, but is significantly less than the \$2,881 million the administration had requested.

Specifically, Congress has denied the administration's request for \$226 million for development of the space station, putting a cap on the level of spending next year at \$205 million. Of this, \$5 million is set aside for the robotics and automation thought necessary for the initial operating capability of the space station. Congress seems concerned that budgetary restrictions in future might hold up space science if the administration persists in its plans for a permanently manned structure from the start.

A cap of \$5 million (with a further \$5 million available upon request) has also been put on development of the solar optical telescope, a 1.25-metre instrument that would form the basis of a solar observatory on the space station. This will mean a significant delay for the project, for which \$30 million had been sought in 1986. Other capped projects include: upper stages (\$122 million); the space telescope (\$127 million); the gamma-ray observatory (\$87 million) and the Galileo spacecraft (\$40 million). The funds allotted to space flight, control and data communications are \$3,398 million, about \$100 million less than requested.

The total appropriated for research and related activities by NSF is \$1,352 million, an increase of about \$40 million over last year. The administration's request had been for \$1,398 million. The conference report of the appropriation bill dealing with NSF (in which differences between the House and Senate are patched up) specifically notes that sufficient resources must be made available to support advanced scientific computing and the ocean

drilling programme, as well as efforts to increase women's and minority participation in science and engineering.

NSF is also given \$115 million for the US Antarctic programme and \$55.5 million for science education, which represents a compromise between the figures urged by the Senate and the House. The foundation also has (to Congress's displeasure) \$31.5 million in its science education budget unspent from last year, so that the total for this purpose will be \$87 million, a dramatic increase on what was spent last year. The Very Long Baseline Array is, however, capped at \$9 million;

astronomers had hoped for \$11.5 million for the project. The increase in NSF's total budget, at close to 2 per cent, is in striking contrast to the 15 per cent increase it got the year before.

Congress has also, for the first time in several years, passed an authorization bill for NSF. The authorization may have already been influential in persuading Erich Bloch, NSF's director, to restore a \$1 million programme on ethics and values in science and technology which he had previously planned to axe. Otherwise, the bill will have little immediate effect, although it is likely to focus attention on particular areas such as fundamental engineering research and research facilities in universities, which NSF is now directed to study systematically. The bill will also give the National Science Board the authority to delegate grant approval authority to the director.

Tim Beardsley

British research funds

Government helps to plug dyke

BURIED in the British government's disappointing announcement last week of its spending plans for higher education and research in 1986-87 is some good news for the research councils, which will have an extra £15 million a year to spend. This is seen to result partly from a sombre report on the loss of British scientists overseas prepared by the chairman of the Advisory Board for the Research Councils (ABRC), Sir David Phillips, and published last week.

The Chancellor of the Exchequer's autumn budget statement last week makes it plain that the recurrent budget of the universities is to be held at the levels proposed in January this year, which have been estimated to entail a cut of 1.6 per cent in real terms. Specifically, the university budget will be 2.5 per cent greater in cash terms next year than this, a rate of increase less than the inflation rate.

The research councils are dealt with more generously. The budget statement says that there will be an extra £15 million a year for each of the next three years, in addition to last year's emergency grant of £27 million (spread over three years). A further £10 million will be distributed to selected university research centres for the purchase of equipment.

The immediate explanation of the government's generosity seems to be that Sir Keith Joseph, Secretary of State for Education and Science, has been persuaded of the reality of the rate at which technically qualified people are being lost to Britain. ABRC has been warning the government regularly about the numbers of scientists moving overseas, but the government has repeatedly dismissed the claim, made most forcefully in ABRC's *Science and public expenditure* statement earlier this year, on the grounds that the

evidence is "anecdotal".

ABRC has therefore carried out a survey among 40 leading research groups in Britain (38 in universities and two at Medical Research Council (MRC) units). It now says that its data reinforce its "firm impression" that there is a serious loss of talent, not only by emigration elsewhere but also to industry and to careers in Britain not based on science.

According to ABRC, the reasons given for the loss of talent are "remarkably consistent": more opportunities elsewhere, better pay and prospects, better facilities, frustration about difficulties in winning research grants in Britain, aggressive recruiting by overseas employers and the greater receptiveness of US industry to new ideas.

Although none of these is new, scientists agree that the gap between the United States and Britain has widened in the past few years. Dr Sydney Brenner, director of the MRC Molecular Biology Laboratory in Cambridge, told ABRC that British university research (with a few exceptions) has not been able to keep pace with international standards and has often declined to a point from which recovery is impossible. Engineering was singled out by ABRC as a discipline in urgent need of support; the two Cambridge engineering departments included in the survey reported that 75 per cent of their recent research students have been lost to overseas appointments.

ABRC has not yet decided how to divide Sir Keith's extra money among the four research councils. But as long as the government continues its last-ditch approach to science funding, the brightest scientists are unlikely to prefer an uncertain home career to the tangible rewards elsewhere.

Maxine Clarke

US accelerators

Virginia sets its sights higher

Newport News, Virginia

Less than a year after being appointed director of the Continuous Electron Beam Accelerator Facility (CEBAF), Hermann Grunder is proposing a radical change of design for the accelerator to be built here on a green-field site starting in 1989 — if Congress approves. Grunder wants to abandon the previously-canvassed combination of room temperature linear accelerator and pulse-stretching storage ring and to use instead superconducting

Cornell-CEBAF superconducting niobium electron accelerator element. Each element includes five radio frequency cavities.

niobium radio-frequency cavities to build a continuous-wave electron accelerator, which is claimed to give superior performance for the same cost.

Part of the interest of the project is political; two years ago, the Southern Universities Research Association stole the project from under the nose of the Argonne National Laboratory. Technically, its importance is that it will be the only source of virtually continuous electron beams in the GeV range.

The proposal is being presented this week to the Department of Energy, which will decide by 1 December which design to support. The new design would consist of two antiparallel 0.5 GeV linacs connected end to end by arcs; electrons would circulate around the ring 4 times for a maximum design energy of 4 GeV. That the accelerator should produce a beam that is almost continuous in time is central to its purpose, as such a beam allows "coincidence" measurements to be made; the new design produces a continuous beam directly rather than relying on a pulse-stretching ring.

The advantages of the new design compared with the old are that the energy spread of the electrons will be reduced by a factor of 10; emittance (a measure of beam size) will be reduced by a factor of 100; and power consumption will be reduced by a factor of three, to 6 MW, because of the much lower energy losses in superconducting magnets. Furthermore, electrons will at any time be available at four different energies, corresponding to the number of revolutions completed.

Grunder was recruited to CEBAF from Lawrence Berkeley Laboratory at the beginning of this year, when enthusiasm for the project was waning. The idea of a high-duty cycle accelerator working in the 0.5–4 GeV energy range has been talked

about in the nuclear physics community since 1976, but it was not until 1983 that the CEBAF proposal submitted by the Southern Universities Research Association was recommended to the government for development funding, after a bitterly contested fight with Argonne National Laboratory. Grunder was tempted to the post of director with assurances that substantial research funds would be available in 1987 and 1988 so that he could conduct a complete technology review.

Grunder describes the superconducting continuous wave design as a "responsible risk" proposal. The concept was first demonstrated in the 1960s; advances in technology since then have made it a desirable alternative that has been investigated at several accelerator research centres and developed most recently at Cornell University. Commercial manufacturers are already able to supply the high-precision high purity niobium cavities used.

The design target adopted is 5 MeV per

metre, but in tests some cavities have already performed well above this level. The cryogenic system, which would operate with low-pressure liquid helium at 2K, is large but well within commercial manufacturers' present-day capabilities, according to Grunder. And the need for very high power klystrons, which were the target of a major development effort for the old design, is avoided altogether. Grunder estimates that the new design can be built for the same or slightly less than the \$236 million price-tag for the previous proposal.

The design energy of 4 GeV will enable quark cluster in the nucleus to be examined, but to look for semi-free quarks many physicists believe higher energies will be necessary. The new design could easily be upgraded later to increase energies two or threefold. Grunder is confident that he will be able to sell his new design to the Department of Energy and to Congress: he would, he says, rather be introducing a new design option even at this late stage than fielding questions about why the superconducting option was not considered.

Tim Beardsley

Embryo research

Chances of legislation fade

MR Enoch Powell MP's Unborn Children (Protection) Bill, already killed twice in the British House of Commons this year, has spluttered into life again, although its chances of prolonged survival are slim. Powell's bill will ban *in vitro* manipulations of human embryos, excepting only cases where a particular pregnancy is to be brought to term. If the bill becomes law, Britain's *in vitro* fertilization programme would halt.

Since the death of the bill, popular with many MPs, by filibuster, Mr Barney Hayhoe, a supporter of the bill, was appointed Minister for Health in the summer cabinet reshuffle, in succession to Mr Kenneth Clarke, an opponent. Hayhoe's personal views, however, are unlikely to lead him to introduce legislation that the Prime Minister, Mrs Margaret Thatcher, is known not to support.

Mrs Thatcher is understood to favour legislation to implement the recommendations of the Warnock Committee, published last year after two years of deliberations. But the government's legislative programme for the coming years, embodied in the Queen's Speech two weeks ago, says nothing about the subject, suggesting that a government bill will not make its appearance for at least a year.

So opponents of embryo research are again left to the device of the Private Member's bill, the draw for which took place last week. Powell himself drew 13th place in the ballot, so will be unable to introduce his bill himself. But several of the 20 names in the ballot are supporters, and one of these, Mr Tom Clarke, drew

first place. But Clarke prefers a less contentious subject that stands more chance of success. Although Powell's bill had a majority of support in the Commons when originally debated, MPs now seem to have moderated their views.

Part of the explanation seems to be the emergence of a group called *Progress*, including physicians and medical organizations who are seeking to educate MPs and encourage a more "rational and humane judgement".

Meanwhile, scientists using *in vitro* fertilization techniques have been registering with the voluntary licensing authority set up by the Medical Research Council and the Royal College of Obstetricians and Gynaecologists earlier this year. Eleven centres have been approved by the authority so far; eight more are likely to apply for a licence soon. And evidence that the authority is not just a public-relations exercise is provided by three centres whose initial applications were turned down, two of which have now modified their work to conform with the guidelines and have been given licences, and the third of which is expected to reapply soon. All the approved projects involve embryos less than nine days old and concern chromosome abnormalities; non-destructive identification of optimum growth media and normal stages of growth; and cryopreservation of pre-embryos. The authority will issue its first annual report in March, when it will give details of the research at the approved centres and identify those that have not applied for a licence.

Maxine Clarke

Japanese honours

Prizes, prizes, prizes . . .

Tokyo

THE first recipient of Japan's new International Prize for Biology is an Englishman: Professor Edred Corner, formerly holder of the chair in tropical botany at the University of Cambridge and now, at almost eighty years of age, in active retirement.

The prize was established this year to celebrate the sixtieth anniversary of the accession of the Emperor, himself a noted amateur marine biologist with his own research laboratories. At ten million yen (US \$50,000) in cash plus a medal and a gift from the Emperor, the prize is meant to rank among the international heavyweights. Indeed, to show its importance the Crown Prince, the Prime Minister and the Minister of Education, Culture and Science all turned out to make speeches at the award ceremony. The Emperor too received Professor Corner (who has met him informally in past years) in formal audience at the Imperial Palace.

NIH veto doomed

Washington

CONGRESS seems likely shortly to overturn a presidential veto of the controversial reauthorization bill for the National Institutes of Health (NIH). The bill, which was vetoed by President Reagan on 8 November, would establish a new National Institute of Arthritis, Musculoskeletal and Skin Disease and a new centre for nursing research. It also lays down guidelines on, among other things, how NIH should use peer review for grant applications and on fetal and animal research.

The House of Representatives has already voted by a large majority to overturn the veto; the Senate seems to be in like mind, but a vote will probably be delayed until President Reagan returns from his summit meeting in Geneva.

The President also vetoed an NIH authorization bill last year, but this year's version has commanded stronger support in Congress. Many of the line-by-line budget recommendations in last year's bill have been dropped. And President Reagan has no objection to the creation of the arthritis institute, having directed NIH to go ahead and create the new institute anyway. It will be formed by partitioning the existing National Institute of Arthritis, Diabetes and Digestive and Kidney Diseases.

But the proposed centre for nursing research and a requirement that NIH spend not more than 5.5 per cent of its income on administrative expenses are regarded by the White House as unacceptable. Nevertheless, NIH officials say, many of the administrative recommendations in the bill are likely to be incorporated into NIH practice even if the presidential veto stands.

Tim Beardsley

It is hoped that the prize will become the "Nobel Prize" of biology. This year, the field chosen for the prize was taxonomy; what it will be next year has yet to be decided. But whatever is chosen, it will be critical to the long-term future of the prize that links are made to a vigorous international network of people willing to recommend candidates.

Professor Corner is the author of several standard works of tropical botany much used by Japanese and other researchers visiting South-East Asia and was responsible for a new classification of the genus *Ficus*; he is also a key figure in the establishment of the modern taxonomical systems for fungi.

Although the International Prize for Biology must rate as Japan's most distinguished award, it is not the only prize being given away in Tokyo this week. Professor Carl Sagan is also receiving ¥10 million as part of the Honda Prize set up by the Honda Motor Company. The prize is for "ecotechnology" and Sagan receives it for his contribution toward "ecotechnological exploration of space, as well as toward establishment of a theory of technological development for the new era of civilization based on a more cosmic viewpoint".

There has been a miniature boom this year in establishing new prizes. In the spring, it was the new "Japan prize" which at ¥50 million rivals the Nobel Prize financially and is intended to reward applications of basic science (see *Nature* 315, 616; 1985). A few weeks ago it was the turn of the Kikawada Foundation. This again went to an Englishman, Professor Christopher Freeman, deputy director of the Science Policy Research Unit at the University of Sussex.

But while Japanese companies are generously giving out prizes to foreigners one after another, they are having less luck in finding an agreeable reason for the failure of Japanese scientists to collect top international prizes. Eight officials of the Nobel Foundation, including board chairman Sune Bergstrom, visited Kyoto last week where they received the special prize of the Kyoto Prize. Speculation that the visit would help more prizes to come to Japan, rather than the United States and Europe, were quickly squashed, however. Committee members pointed out that science is international, and that language and distance from Sweden are no barriers to receipt of a prize. An explanation of why a Japanese scientist has never received the Nobel Prize for Physiology or Medicine is rather to be sought in lack of basic research effort. And that might suggest that the new foundations would have served their country better by making up for the lack of funds available for original research in Japan rather than seeking glamour from abroad.

Alun Anderson

French defence

Smaller warheads planned

FRANCE is to develop new miniaturized nuclear warheads to "punch holes" in other people's defence systems, according to the French Minister of Defence, Paul Quilès. In a rare public account of French nuclear policy, Quilès said last week that he had set the Commissariat à l'Energie Atomique several ambitious targets to be achieved by 1994, when the first of a new series of nuclear submarines will come into service.

The miniature warheads are among these objectives, and seem to be a kind of French response to US plans to develop defences against ballistic missiles, the Strategic Defence Initiative (SDI). The more attention the superpowers pay to strategic defence, Quilès said, the more necessary becomes "the penetration capacity of our missiles . . . to our policy of nuclear dissuasion".

Quilès nevertheless repeated last week his government's opposition to SDI. The period when the Soviet Union and the United States were installing the new technology would be a "particularly critical time" for world security, while SDI would be ineffective against the short and medium range missiles aimed at Europe. But it is plain from what he said that France is most of all concerned that the new interest in strategic defence will permit an improvement of the conventional Soviet anti-ballistic missile system already deployed around Moscow. The use of "stealth" technology, both miniaturization and the use of non-reflecting radar coatings, is a natural countermeasure.

In passing, Quilès has also explained French sensitivity about the present programme of nuclear testing in the Pacific, indirectly responsible for the sinking of the *Greenpeace* ship in New Zealand and, ironically, for the resignation of Quilès's predecessor, Charles Hernu. France is obviously committed to a new programme of warhead technology, for which testing is considered essential. In France, there appears to be no opposition to the programme.

From what Quilès said last week, it also seems that the French navy rather than the air force will be the spearhead of the new strategy. Noting that the mere presence of British nuclear submarines in the South Atlantic had kept the Argentinian navy in port during the Falklands war, he announced that France would add another nuclear submarine to the six ordered since 1984. But Quilès effectively squashed air force hopes to build a new land-based strategic missile, saying that the resources would be better spent on the improvement of submarine missiles. The existing "park" of 18 missiles in Haut-Provence will, however, be retained.

Robert Walgate

Computer language

When to go back to BASICs

Dartmouth, New Hampshire

BASIC is being debased, says one of its creators, Professor John Kemeny of Dartmouth College. Kemeny, still at Dartmouth's department of mathematics, where BASIC was developed more than twenty years ago, is now calling for a halt to the development of inferior versions of his never-patented language, saying that they are corrupting its purposes and causing chaos in the computer industry as well.

In 1963, Kemeny and his colleague Tho-

mas Kurtz changed the face of computer science forever by inventing BASIC, now probably the most widely used computer language in the world. Their objective was to create a novel learning tool for students. To begin with, they installed a collection of teleprinters linked with a mainframe in one part of a students' recreation room.

The arrival of the microprocessor made sure that BASIC would not be just a Dartmouth teaching aid. Now, after twenty years, Kemeny reckons that there are more than 100 versions of his language, most of them so inferior that he and Kurtz have become seriously concerned.

Kemeny says that the later versions violate the philosophy of the original. If only users would go back to BASICs, educationalists would have a superior tool, while programs written for one microprocessor would be found to work on others. BASIC (which stands for Beginners' All-purpose Symbolic Instruction Code) began, he says, as a device for giving undergraduates simultaneous access to Dartmouth's GE mainframe computers. With the volume production of microprocessors in the 1970s, however, the language began to be used extensively in various forms. Because the memory of the early machines was limited, programmers were at first compelled to improvise, simplifying BASIC and specializing it to fit the memory of small machines.

Kemeny's frustration is that, even though the microprocessors now available do not have the limitations of those being manufactured 20 years ago, the omissions

from BASIC used by the early programmers have not been reinstated. But, Kemeny says, "these machines are not toys, but very powerful computers. The IBM PC I have at home is not a particularly expensive model, but it is more powerful than the original timesharing machine here at Dartmouth." That is why, Kemeny says, many of the BASIC programs now on offer "just don't live up to what any computer scientist would expect of a good language in 1985".

Two years ago, Kemeny, Kurtz and three other computer experts accordingly set up a company to promote the fundamentals of BASIC languages, and to engineer improvements of software developed by other computer scientists. Inevitably, the company is called True Basic.

Kemeny predicted 20 years ago, when opening the computer centre at Dartmouth College, that every home would have a computer terminal within a quarter of a century. The unexpected arrival of the microprocessor has almost made that prediction a reality, but the lack of a common computer language is still an impediment. So one of the goals of the Kemeny group is to develop the language that will make the vision a reality.

So far, the group has developed compilers for the IBM PC and for the Apple Macintosh that will allow them to respond to TRUE BASIC. Two new microprocessors to be launched onto the Christmas market this year will also have such compilers. According to Kemeny, because the compilers written for the individual models embody the necessary changes, programs written in TRUE BASIC for any of these models will run successfully on any other. **Bill Johnstone**

India against AIDS

New Delhi

ALARMED by reports of AIDS (acquired immune deficiency syndrome) in Pakistan, both India and Bangladesh are taking precautionary steps to keep out the AIDS virus. The Indian Council of Medical Research (ICMR) has set up a task force headed by the ICMR chief Dr V. Ramalingaswami. A similar panel under Professor Nurul Islam, director of the Dhaka Institute of Postgraduate Medicine, has been set up in Bangladesh.

No confirmed case of AIDS has been reported either in India or in Bangladesh. But Professor A.N. Malavya of the All-India Institute of Medical Science in New Delhi and a member of the task force says it is only a matter of time. The major aim of the task force is to educate both the doctors and the public about AIDS without creating a scare and to keep tabs on vulnerable groups including haemophiliacs, homosexuals and a significantly large population of eunuchs besides the prostitutes in ports such as Bombay, Calcutta, Madras and Vishakapatnam.

Cases showing AIDS symptoms will be referred to any of the dozen medical institutions to be designated as reference centres. The National Institute of Virology in Pune is being equipped to screen for AIDS antibodies and viruses in blood samples of suspects. The task force is evolving a detailed questionnaire to be circulated to private and government doctors and an educational campaign is planned. But the Indian government does not want to divert huge funds to an anti-AIDS programme as there is no evidence of AIDS yet.

In Bangladesh, the AIDS committee has been asked to prepare a plan of action for the prevention of AIDS. As well as evolving a programme for surveillance, detection and treatment, the committee intends to propagate Islamic ideals on the evils of promiscuity. People have stopped buying imported second-hand clothes following a rumour that they might be contaminated with AIDS virus, and Bangladesh newspapers have asked the government to screen incoming passengers from the West.

K.S. Jayaraman

UK laboratory animals

Debate on legislation ahead

THE British government's Animals (Scientific Procedures) Bill, published last week, will be debated in the House of Lords this month. The bill follows the proposals outlined in two white papers (policy documents), Cmnd 8883 in May 1983 and Cmnd 9521 in May 1985, and is intended to replace the Cruelty to Animals Act of 1876 (see *Nature* 315, 267; 1985).

Attempts to reform existing legislation on laboratory animals have failed in the past because of strong protests from animal rights groups and reluctance of members of parliament (MPs) to become embroiled in the issue. The new bill is supported by the middle-of-the-road animal welfare groups, who advised in drawing it up, but is violently opposed by the extreme animal rights groups who are against any experiments on animals being made legal.

The bill requires that a project licence be obtained before work can begin, con-

trols breeders and suppliers of animals and establishes a committee to provide independent advice to the Home Secretary. All research establishments must appoint a named person to care for animals, there will be heavier penalties for offences and controls on the re-use of animals.

A significant provision is the explicit acknowledgement that pain is caused to animals; licences will be issued only if the Home Secretary is satisfied that the benefits outweigh the adverse effects on the animals and the licence requires that pain, distress and discomfort are minimized.

The bill has wide support from scientists and welfare groups, and its passage through the House of Lords seems assured. But the Commons is very different. MPs have traditionally been extremely reluctant to favour any legislation that makes them seem to be supporting "cruelty" to animals in the eyes of their constituents. **Maxine Clarke**

British research councils

Budgets on a shoestring

PROFESSOR Bill Mitchell, new chairman of the largest British research council, the Science and Engineering Research Council (SERC), presented the organization's annual report last week. Sir John Kingman, who was chairman until the end of September, says in the report that the severe financial pressure of recent years has resulted in losses sometimes "out of all proportion to the money saved", particularly in the lack of provision of operating costs for big-money facilities. "The truth of the matter is that the United Kingdom is trying to maintain its science base on the cheap", said Kingman.

Mitchell, taking a more optimistic line than his predecessor, congratulated Kingman on "coping so well in difficult circumstances" but said that the work described in the report was not that of a "demoralised science and engineering community". But like Kingman, he stressed the role of basic research in making discoveries of "economic significance".

One new source of money in the science arena is a joint Ministry of Defence (MoD)/SERC programme. SERC welcomes the influx of money (MoD and SERC will each provide 50 per cent). Projects will be subjected to peer-review in the normal way, and will be restricted to unclassified fields. SERC will assess the scheme next year and "reconsider" if any of its conditions are not met.

The highlight of 1984 was the production of the first neutrons by the Spallation Neutron Source (Rutherford Laboratory, near Oxford) in September. At the Synchrotron Radiation Source (Daresbury Laboratory, near Manchester) the "wiggler" beamline enabled the first enzyme crystal, phosphorylase *b*, to be monitored as it performed its catalytic reaction. Unexpected order-disorder transitions have been found and people are queuing up to use the device which measures 40,000 reflections per second.

In 1984 the Isaac Newton, Jacobus Kapteyn and Carlsberg Meridian Circle telescopes began operation, the Active Magnetron Particle Tracer Explorer satellite was launched and the Anglo-Australian Telescope has allowed the most distant galactic objects yet known to be seen. But the Royal Greenwich Observatory may soon stop participating in the international time determination programme (see *Nature* 31 October, p.754); SERC has decided to support observational astronomy at the expense of other projects.

Engineering science has received increased financial support during the past 10 years so that it now makes up 20 per cent of SERC's budget. SERC is reviewing the effectiveness of its engineering programmes and will decide whether to shift priorities again, or even whether to change its own name (to STRC, T for

technology) in February 1986. Similarly, SERC is reviewing its position on chemistry research, an area that has lost ground in the past three years.

Another controversy caused by government cuts is the question of British membership of the European Organization for Nuclear Research (CERN). Reduced money to SERC has coincided with an increased subscription to CERN and it is likely that some experiments will stop completely, damaging Britain's reputation as a reliable partner in international collaborations. The decision is in the hands of the government, at present considering the recommendations made to it

Soviet plan

More goods, more science

THE "Draft Basic Guidelines" for the Soviet Union's Five-Year Plan (1986-90) are, as usual, not so much a detailed economic programme as a manifesto eulogizing the Soviet way of economic life. The preamble extols the progress in the "scientific and technical revolution" during the past five years. It says that nuclear power now accounts for one tenth of all Soviet generating capacity and that the Soviet Union, "which earlier took first place in the world in terms of oil extraction", now holds a similar position with regard to natural gas. Free textbooks are now provided in schools, the housing problem is "being consistently solved" and the natural wealth of the eastern and northern regions of the Soviet Union are being opened up at an "accelerated rate".

The guidelines for the future present a somewhat less happy picture. The "supreme goal" in the next five years and for the remainder of the century is the "steady upsurge of the standard of living" of the Soviet people by raising the efficiency of production. In pursuit of this aim, the food programme (Brezhnev's last legacy to the Soviet people) is to be implemented to ensure the "scientifically substantiated norms of rational consumption", while there is a package of measures to improve the health service. There have been complaints in the Soviet media about poor performance in the health service, perhaps because the energetic anti-alcohol campaign led to the neglect of other aspects of health.

The emphasis on the citizen-consumer reveals, perhaps, how much this sector has been neglected in previous plans. Production of non-food consumer goods is to be increased by more than 80-90 per cent, and the "volume of services" delivered will, according to the forecasts, be more than doubled. But other targets, too, are set equally high — gas extraction at 60-80 per cent more than in the current quin-

quennium and nuclear power increasing between five and sevenfold. In industry, there is to be a general inventory of "fixed production capital", and more than one third of it renewed. The opening up of Siberia and the far east to industry is to continue, although there is now increased emphasis on environmental protection.

In science, the role of the Soviet Academy of Sciences as co-ordinator of research is to be "enhanced", as also will be the role of the academies of the union republics. The draft plan speaks of utilizing the scientific potential of the higher education system, and expanding the research and development work in the universities. There is to be closer interaction between the research facilities of the academies, the universities and the specialized institutes of the production sector, and "progressive new forms" of research organization will be sought.

Several scientific fields are listed for special development, including theoretical and applied mathematics, information science, cybernetics, particle, nuclear and solid-state physics, micro and quantum electronics and also research into nuclear and non-traditional energy sources. The "scientific principles" of catalysis, chemical technology and biotechnology are to be "elaborated" and the mass production of personal computers is to be "organized".

The supply of modern instruments, materials and other necessities to research facilities will be "substantially improved".

The guidelines are nevertheless unclear about the relative roles of pure and applied science, saying that the "fundamental task" of the current plan is to "strengthen ties between science and production", while, at the same time, "priority significance" is to be given to fundamental research which "predetermines the attainment by social production of a qualitatively higher level".

Vera Rich

by the Kendrew committee (see *Nature* 315, 619; 1985). Money for nuclear physics and astronomy research has generally declined in the past ten years relative to basic science and engineering research. Even so, SERC says it needs an extra £30 million a year by the end of the decade to support a programme of research in the basic sciences "commensurate with the country's standing as an advanced European country . . . and to provide the trained manpower the country needs".

SERC is submitting its first-ever corporate plan to the Advisory Board for the Research Councils (ABRC) this week, and will publish it next month. ABRC will use the corporate plans from all the research councils in its annual advice to the government, in which it makes its case for more money for science. **Maxine Clarke**

Foreigners' tenure at Tsukuba

SIR—I should like to add a gloss to Alun Anderson's fair report on the "turmoil over treatment of foreign staff" (*Nature* 10 October, p.465) at Tsukuba University, self-proclaimed champion of the internationalization of university education in Japan.

Four foreign staff members, including myself, expected to be given long-term contracts not because "some supporters made affirmative responses" to them, as Tsukuba's president, Nobiyuki Fukuda, says, but because the due process for their appointments had been put in train: the vice-president in charge of education, *ex officio* member of the personnel committee that makes final decisions in personnel matters, first ascertained the need for our posts at the departmental level, then discussed his proposal to give us long-term contracts at a meeting of the president and the five vice-presidents, none of whom voiced any opposition. Thereupon he instructed the department heads to let us know that we were scheduled to get tenure. The department heads prepared the formal applications to be submitted to the personnel committee. I therefore think that our expectations were not "extremely strange" as Mr Fukuda believes, but only reasonable. What is strange is that the final authority on personnel matters was not given a chance to make its decision as neither the departmental applications nor the supporting proposition of the vice-president were considered by a meeting of the personnel committee — apparently both were blocked when the vice-president was sacked.

While it is true that there is no final definition of "internationalization", I think there is agreement on certain ingredients that it must contain, such as non-discrimination on grounds of nationality, transparency and minimum civility. Tsukuba University is still in want of all of them, I am afraid. Anderson amply illustrated that foreigners at Tsukuba are not treated "just like anyone else". It might be added that Tsukuba did not avail itself of the opportunity the new law offers to give tenure to foreigners. For foreigners at Tsukuba, "tenure" means just 5-year contracts, while every Japanese staff member gets real tenure from the start. Foreign lecturers have to carry a teaching load of 12 hours per week whereas their Japanese colleagues average five.

The rule limiting employment of foreigners without tenure to four years resulted from the unwillingness of university authorities to speak their mind clearly. Not all foreign lecturers have always performed their task satisfactorily. The university therefore introduced a system grading each foreigner (but no Japanese) each year as A, B or C. Yet rather than tell the Cs to improve or leave, all lecturers had to quit, the As along with the Cs. The

announcement was made in writing, with no explanation.

"Inexplicable silence followed by brazen behaviour", a Japanese attitude regarded by many Westerners and Japanese as a serious obstacle to internationalization, also characterized the recent events at Tsukuba that Anderson described. No wonder then that Tsukuba is seen as becoming more parochial rather than internationalized. To dismiss this view as "nonsense", as Mr Fukuda does, does little to solve the problem.

Reputable PhDs

SIR—"A PhD is supposed to be a training in research" says Beverly Halstead (*Nature* 316, 760; 1985) and therein lies his problem. I suspect that some proportion of every thesis (for example the research training part) will not meet the standards of the existing avenues for publication. That is not to say that some of this proportion would not be useful to someone embarking in that particular area of research. Thus there exists a case for making theses, in their entirety, more readily available globally through some other means (for example microfiche).

Attempting to distinguish major from non-major contributions to science would be headache enough, but differentiating between reputable and non-reputable journals is a job I leave for Beverly Halstead. I look forward to his published list appearing in these columns.

Units are for people

SIR—Although no system is proof against mistakes, spectacular events, such as the apparent misprogramming of a space-shuttle computer (*Nature* 315, 702; 1985), highlight the usefulness of an agreed universal system of units. D.C. Jolly (*Nature* 316, 480; 1985) enters an impassioned case for the foot, pound, second system, as an alternative to SI and pleads for a counter-revolution. W.G. Rees (*Nature* 317, 10; 1985) has suggested an ingenious system which differs from the foot, pound, second system by a possibly tolerable amount, such that c , G and $4\hbar$ become exact multiples of his base units.

Unfortunately, his suggestion is impractical since, for example, we cannot yet measure all of the fundamental constants and atomic phenomena with the required accuracy. Indeed, as we do so, the SI units

too will incorporate the fact, for the Conférences Générales des Poids et Mesures will revise the recommended definitions of the base units accordingly, as they have with the second and metre — but without altering their size.

While it is tempting to argue for a change to a "natural" system of units, we ought to recall that part of the appeal of the c.g.s. system to our nineteenth century forebears stemmed from its use of "natural" quantities associated with our planet. Who can be sure that the fundamental constants e, c, h , G and so on will not have been replaced by an ever deeper set by the end of the next century? Moreover, a system only appears natural if the units are appropriate to the discipline with which the proposer is most familiar — what is "natural" for the physicist is not necessarily so for the biologist, chemist, artisan or "man in the street".

We might yet, if we chose, be able to recycle some of our earlier units instead, for G is near enough unity in the Gunter link, troy grain and lunar month system of units, and the Planck constant essentially 1 attoleague¹ megascruple² centiweek³ (British nautical leagues, apothecaries scruples and sidereal weeks). Professor Kenneth Meyer, at the University of Cincinnati, has shown how unit conversion tables (in the *Handbook of Chemistry and Physics* and elsewhere) together with a microcomputer allow such combinations to be found — even an exact one by an undetectable massaging of the magnitude of the earlier unit! I suggest though that readers wait for the forthcoming CODATA evaluation of the recommended "best values" of the fundamental physical constants before searching for the best such combination of earlier units to six decimal places!

Sir Henry Wellcome

SIR—In the article on the Wellcome Trust and Foundation (*Nature* 24 October, p.662), you refer to them as being set up under the will of Sir Henry Dale. I believe that it was Sir Henry Wellcome who in his will created these institutions.

As a young prescriptions clerk in Rochester, Minnesota, Wellcome was encouraged and supported by Dr W.W. Mayo to improve his education and not to be satisfied with his position. Mayo had been taught chemistry by John Dalton before emigrating to the United States. His sons, William and Charles Mayo, created the Mayo Clinic.

Evolution and education

SIR—Your erroneously titled "Californian setback for evolutionists" (T. Beardsley, *Nature* 5 September, p.3) described an unprecedented recommendation by California's Curriculum Commission: that no science textbooks be adopted for grades 7 and 8 unless the books be revised to give proper treatment to evolution and human reproduction, among other subjects. This was a significant defeat for creationists and others who try to subvert science education in this state. The defeat was certified on 13 September, when the Board of Education accepted unanimously the Curriculum Commission's plan.

Beardsley erred when he attributed to California an "antidogmatism law". No such law exists. But the Board of Education has an antidogmatism policy, which dictates: "That, on the subject of discussing origins of life and Earth in public schools: (1) Dogmatism be changed to conditional statements where speculation is offered as explanation for origins. (2) Science should emphasize 'how' and not 'ultimate cause' for origins."

This grotesque declaration, adopted in 1972, is noteworthy for many reasons. First, it is blatantly dogmatic. Second, it can be explained only as a device for appeasing creationists and for abetting their attempts to distort the teaching of science. Third, it erects a wholly specious, intellectually indefensible demarcation between discussions of "origins of life and Earth" and discussions of all the other subjects that science addresses. Fourth, nobody can say precisely what the policy means or requires, because none of its terms — dogmatism or conditional statements or speculation, for example — is defined. Fifth, in an antic, confused decision rendered in 1981, a judge of California's Superior Court suggested that the policy should apply not only to discussions of "origins of life and Earth" but also to discussions of organic evolution. Sixth, since 1981, creationists in California have relentlessly and conspicuously invoked the policy (and their own interpretations of its surrealistic language) during efforts to vitiate or suppress discussions of evolution in textbooks and in science classes. Seventh, because the policy's only evident purpose is to serve the adherents of a particular religious dogma, the policy's constitutionality is (to say the least) questionable.

WILLIAM J. BENNETTA
PO Box 26603,
San Francisco, California 94126, USA

Tim Beardsley writes: In the 1981 case referred to by Bennetta, Sacramento Superior court Judge Perluss not only upheld the validity of the antidogmatism policy but also ordered the State Board of Education to disseminate it to all interested parties; the policy may therefore be not entirely without legal force. □

Teenage SCOPE

SIR—Your article entitled "What to make of nuclear winter" (*Nature* 19 September, p.189, mentions "the working party called the Scientific Committee on Problems of the environment (SCOPE) set up three years ago by the International Council of Scientific Unions (ICSU)". This sentence give a wrong picture of our committee. As you might know, SCOPE is one of the ten scientific committees of ICSU and was established in 1969 to assemble, review and assess the information available on man-made environmental changes and the effects of these changes on man.

In 1982, the SCOPE General Assembly decided, at the request of ICSU, to appraise the state of knowledge of the possible global environmental impacts of nuclear war. That project, called ENUWAR, may have been the most important of some ten international scientific projects undertaken by SCOPE during the past triennium, but it does not overshadow the contribution of SCOPE during the past fifteen years to the advancement of scientific knowledge on many problems of global environmental concern.

Velikovsky's evidence?

SIR—Lynn Rose's defence of his interpretation of the Venus Tablets¹ may be seductive, but his conclusion is neither as inevitable nor as secure as he argues. He states that the tablets "strongly support Velikovsky's theory that Earth has undergone catastrophic orbital change within historic times". However, there is no explicit connection between the tablets and Velikovsky's catastrophes. Indeed, the change implied in the shape of Earth's orbit is a far cry from the intersecting orbits discussed by Velikovsky. The only philosophically justifiable conclusion is that Rose's interpretation of the tablets "is consistent with" Velikovsky's theory, not "strongly supportive".

In contrast to Rose's insistence on ignoring as few of the observations in the tablets as absolutely necessary, he argues his case favouring Velikovsky while ignoring a plethora of contradictory data. The falsification of Velikovsky's scenario provided by Greenland's Dye 3 ice core² is corroborated by ocean sediments and bristlecone pine rings³ and the revised late-glacial Swedish varve chronology⁴. Either their mere existence contradicts Velikovsky or they do not contain debris suggesting a catastrophe. Velikovskian catastrophes are neither indicated by nor necessary to explain the natural stratigraphies of the Holocene.

Furthermore, according to Rose's own

work with Vaughan⁵, the sequence of orbital changes implied by *Worlds in Collision* that conserves angular momentum without increasing orbital energy starts with the untenable condition of Earth closer to the Sun than Venus now is. Surely such a severe physical constraint⁶ is to be accorded more weight in assessing the validity of Velikovsky's theory than an idiosyncratic interpretation of the enigmatic Venus Tablets.

The Terminal Cretaceous Event 65 million years ago, whatever it was, left unambiguous, worldwide signatures of iridium⁷ and soot⁸. The catastrophe Velikovsky conjectured within the past 3,500 years left no similar signatures. In this light, advocating the validity of Velikovsky's scenario, as Rose does, strains the bounds of credulity, both scientific and philosophical.

If the Venus Tablets preserve authentic observations, however disguised by copying errors, then explaining the discordant observations needs to be accomplished with new insight. For example, John D. Weir has suggested to me that if a formerly very bright comet periodically altered the sky's brightness, then the dates of appearances and disappearances for Venus would be affected. The debris from the disintegration of comet Encke 4,700 years ago, discussed by Clube and Napier⁹, would be a possible agent. The clay of the Venus Tablets is far too fragile a foundation upon which to justify a new physics for the rationalization of Velikovsky's theory.

Help wanted

SIR—In collaboration with Professor Richard Gregory, Professor Dorothy Hodgkin, Sir Fred Hoyle, Sir Peter Medawar and Dr Jonathan Miller, I am preparing an anthology of science writing, to be published by Basil Blackwell. The intention is to bring together a wide variety of pieces, ancient and modern, of varying length, and drawn from all sectors of science, the sole criterion being that of literary excellence. We would be delighted to receive suggestions from readers of *Nature* regarding items suitable for inclusion in what we hope will prove to be a work of sheer aesthetic and intellectual delight.

**Agar...automatically
from powder to plates
in less than 90 minutes...**

**Up to 8 liters
(400 plates) of
high-quality
agar whenever
you need it**

Any laboratory can have high quality agar whenever it's needed thanks to two benchtop instruments — the Agar-Matic, an 8 liter sterilizer, and the PourMatic, a self-stacking carousel-type petri dish filler.

Simply add water and dehydrated medium to the Agar-Matic. Then set it and forget it. This automatic sterilizer does the rest. Fresh, chemically superior agar or nutrient broth is ready to pour in less than an hour. If you're not back in time, the agar will be maintained at the desired pouring temperature.

By adding the PourMatic, agar can be sterilized, cooled, poured into plates and stacked... all automatically in only 38" of bench space while you tend to more important activities. Microprocessor control assures dependability and minimizes operator supervision.

Agar sterilizers from 3 to 130 liters are also available. Send for 16-page catalog: New Brunswick Scientific Co. Inc., P.O. Box 986, Edison, N.J. 08818, (201) 287-1200 or (800) 631-5417.

Industrial power by research?

China's science is in the process of being harnessed to ambitious social and economic goals. This survey of science in China may suggest whether the venture will succeed.

Will China make it? And how soon? Or will the present still-short period in China's recent history prove to be another aberration, like the Great Leap Forward (1960–66) or the Cultural Revolution (1966–76)?

In China now, opinion is unanimous. The largest nation on the Earth is at last on the road to becoming an industrial power matching in prosperity and creativity the most successful nations elsewhere in the world. The job will be done by adapting science and technology to China's distinctive talents, of which the Chinese are self-conscious and proud. The task, of course, will take time — half a century or even more — but what is that by the yardstick of China's three millennia of recorded history?

The optimism is almost palpable — and is the only credible explanation of people's apparent willingness to endure a degree of personal deprivation, material and otherwise, that still shocks people from the West.

This survey of science in China is inevitably incomplete, less a survey in the strict sense than a reconnaissance. The government of China claims that there are more than 4,000 independent research organizations in China, which, if true (there are problems of definition), implies that the account that follows is based on a one per cent sample which is, moreover, biased towards institutions whose reputations travel.

Even so, there are good reasons to believe that important generalizations can be safely made. First, there is the curious phenomenon, entirely unfamiliar in the West, that government officials are the first to agree that there are obvious shortcomings in their organization for China's objectives; often, they will go on to explain what they plan to do about these problems. Second, there is the uniformity of the common conviction that the ship is sailing in the right direction: it would be churlish to ask whether China has always been so certain of itself.

China is also a Marxist state, in this as in many other respects the largest anywhere. Those who may think that the political system must surely be irrelevant to a description of what laboratories are like and to an appraisal of how the system is orga-

nized are profoundly mistaken. The truth, in China, is that communist principles and organizations influence everything, not only the distribution of power between the Party and the government but the conditions under which ordinary people live and researchers go about laboratory work. China's goal is not merely to become an industrial power of the first rank, but to remain a communist state.

For the time being, the disciplines and controls stemming from the party's influence, not to mention the way in which the patriotism engendered by the present optimism is strengthened by the party's control of press and television, may help to keep China moving forward single-mindedly. It is an absorbing but unanswered question whether, somewhere along the road, intolerable contradictions will arise. Meanwhile, it is best to remember that the break with the Soviet Union in the late 1950s came about because the then Chinese leadership believed itself alone to be following the true precepts of Marx.

Enthusiasm

Much of the enthusiasm of the present nevertheless springs directly from the way in which the system that gave rise to the Cultural Revolution is now being changed; "reform" is the slogan. The reopening of China to the outside world is one sign of the change; China has gained a torrent of tourists, and is now looking for the generous transfer of technology from the West. The decentralization of the power to transfer administrative (but not political) decisions to provincial governments and operating agencies of the government is another; efficiency is the goal. An uncovenanted side-effect may be that able people no longer feel that only the local general secretary of the party has real power.

The most daring of the reforms so far has been the much-publicized decision that peasants may sell their produce on free markets wherever they have access to them. One result has been a sharp increase of agricultural production (to which other influences have contributed), another is the persisting argument between the party purists and pragmatists about the propriety (and wisdom) of letting loose the genie of the search for gain.

Yet for now, the economic consequences of reform are its sufficient justification. During the past five years, agricultural and industrial production together have increased at a rate of more than 10 per cent a year, too fast for comfort. So the new five-year plan, presented in outline to a National Party Conference in September, will be based on the assumption that growth in future will be moderated to between 7 and 8 per cent a year, just about enough to meet the objective of the Party Congress in 1982 that there should be a fourfold increase of production by the end of the century.

Enterprise

The temptation to attribute these changes to the mild breath of free enterprise in the economy is strong, but would be mistaken. Obviously, economic motives have helped, but only marginally. Eighty per cent of the population of China still lives on the land, and only a tiny fraction of these people, those who by chance live near cities allowing the import of produce other than through the state purchasing agencies, are able to benefit.

The countryside has become more productive for two other reasons, the improvement of crop strains in the past few years (and their general and rapid adoption under the party's influ-

Explanation of a map

To many in China, the choice of an eighteenth-century map, however interesting, to decorate the cover of this special issue of *Nature*, will seem inappropriate. Why not a rocket taking off, or a power station, or a textile mill or something else that will represent the modernity of emerging China? The choice, deliberate as it is, is intended to be symbolic in several different ways.

First, everybody visiting China must be aware of China's sense of its own antiquity, from which may derive its people's confidence, fatalism and patience; this map puts China at the centre and the rest of the world around the edges.

Second, the map shows China as a kind of island which, in spite of the opening to the outside world in the past eight years, China still is. The changes of the past few years have been dramatic, but China is so huge that its contacts with the outside world remain geographically peripheral; the special economic zones are the modern equivalents of the coastal concessions of the eighteenth and nineteenth centuries. In the cities, foreigners are lavished with hospitality but are otherwise still mostly isolated in the foreigners' hotels from which occasionally they venture to spend foreign currency in the shops set aside for foreigners. □

ence), and the concomitant rapid growth of rural industries (which is China's intended but still untested defence against the usual flight from rural to urban slums). In other words, the science of plant-breeding has already contributed substantially to prosperity.

The same is true in manufacturing industry, but to an unquantifiable extent. Indigenous capital investment in new factories has certainly played an important part. So too have the countless joint ventures with overseas high-technology companies which, by creating enterprises for the indigenous manufacture of modern equipment such as telephones, allow the value of China's output to be increased without a proportional investment of indigenous skill. (McDonnell Douglas, for example, will soon start shipping to Shanghai kits from which civil aircraft will be assembled.) Vast as China is, it seems generally and realistically to be accepted that it will be a long time before the country's technical community can sustain the government's industrial ambitions.

Impediments

Several obvious impediments are listed in what follows, but in a spirit that needs careful definition. China, by its own assessment, is a developing country that has somehow survived two centuries of foreign occupation and civil war to enjoy less than a decade of single-minded social and economic progress. The most remarkable feature of the present state of affairs is that China's ambitions cannot be laughed out of court. Another is that the government, whatever its political character, appears to have a realistic appreciation of what the difficulties will be.

The most serious obstacle to continuing change is the shortage of technical skill. In university departments and research laboratories, the lack of technicians means that creative people spend much of their time on laboratory chores. Nowhere are there the small armies of people needed to make headway quickly in fields where numbers matter — writing software for digital telephone switching systems, for example.

Yet it is only within the past few years that, on the academic side, China has had the confidence to mount its own PhD programmes in universities and research institutes. In applied research, the most glaring shortage is of people competent to mount research and development programmes within the framework of industrial enterprises. The most acute shortages appear to crop up in the medium-sized enterprises which, elsewhere, are the chief agents of technical change.

The government acknowledges the difficulty. The next five-year plan will see an increase of recruitment to the universities (by a modest 20 per cent to an annual intake of 500,000 students), but the chief emphasis will be on the training of technicians, in formal technical colleges and in vocational schools linked with the factories. If there is to be an expansion of the university system that would give China a participation rate comparable with that of say Britain (let alone the United States or Japan), that will be postponed to a later plan.

Often, it emerges in conversation (see p.219, Beijing polytechnic) that there are influential people who think China does not need to follow the models established elsewhere; if the enterprise is properly planned (as communist ideology says it should be), a single research institute can take responsibility for the development carried out in the West by several competing enterprises, so that technical skill will be used more efficiently. There are the makings of future rows in this difference of opinion, but not yet.

Difficulties

A much more serious difficulty is the way the research enterprise is organized. China does not, at present, benefit as it might from the skills at its disposal. China's public institutions and enterprises — until recently, there were no private enterprises — are organized along the lines now familiar in the Soviet Union. At the very top, government ministries more often correspond to what would be called executive agencies in the West (which explains why, in China as in the Soviet Union,

there are so many of them). Their job is not so much to make policy that others follow, but to ensure that predefined tasks are executed. So a hypothetical ministry of electric power will not merely build and operate electricity generating stations but also build factories in which to manufacture generator sets and the other equipment needed. To ensure a supply of trained people, it will found a university or college at which promising young people can be trained, and it will then undertake to provide those whom it employs with housing and their children with schooling. A ministry or other large public organization is like a state within a state, commanding the undivided loyalty of its employees, but bound to them by the duty to provide the necessities of life.

Revolutions against previous feudal systems have plainly been less radical than their sponsors have imagined. In the Chinese Academy of Sciences and its institutes and at other academic institutions, the paternalism of the institution towards those whom it employs is taken for granted by both parties. Specifically, those graduating from universities will be assigned to jobs in commerce or industry within quotas provided by the government, but may also apply for posts at research institutes. If successful, the corresponding quota slot remains unfilled, and the student stands on the lowest rung of the research ladder which may, with further success, offer the chance of a PhD course, perhaps overseas, or even a fellowship somewhere else. Promotion within the institute is the rule; sometimes, a transfer to an administrative post with the parent organization is possible. Salaries are poor but costs are low; people pay a few yuan a month (\$1=2 yuan) for the apartments with which they are provided. At suburban research institutes, there will be communal facilities such as a pond stocked with carp. The University of Beijing runs no fewer than three schools for the education of the children of the faculty.

Benefits

The benefits of such arrangements are plain; young people joining a research institute know that they must expect to succeed, at least in the first instance, within that framework. They are accordingly loyal, diligent and respectful. But if, with the passage of time, they should be less than wholly successful, there is no incentive for them to move elsewhere, and every incentive for them to stay. Research institutes become families, greatly extended families. The managers of the system now recognize that the consequence is often stultifying immobility, and several attempts to tackle the difficulty are under way — the secondment of people to factories without loss of academic status, limited postdoctoral fellowships and the like. But the effects of these innovations will be only marginal while the economic system depends as much on rewards in kind.

The doctrine of the self-sufficient public agency is another impediment to the effectiveness of the professional research cadres. Even if it had been possible to buy liquid nitrogen and

Chinese names confuse

THE romanization of Chinese characters is a problem and in an effort at least to standardize and simplify it the Chinese government adopted in 1979 *pinyin* as the official romanization system. The *pinyin* system underpins the drive to establish a nationally-recognized spoken language. This system has been followed as far as possible in what follows. Certain spellings such as Beijing for Peking are now becoming familiar but Guangzhou for Canton perhaps less so. Shanghai remains the same, but the Yangtse river which enters the sea at Shanghai is now written Changjiang. The structure of Chinese personal names presents additional problems but two-syllable (two-character) components are often now written as a single word. Two of the most famous names, Mao Tse-tung and Chou En-lai, are now rendered Mao Zedong and Zhou Enlai. Hong Kong, which has some claims to retain this spelling at least for the present, has not been referred to as Xianggang, the *pinyin* romanization. □

other cryogenic gases on the industrial market, the suspicion must remain that the Chinese Academy of Sciences would have preferred to make its own, for fear otherwise of having to depend on other agencies, with different goals, for strategically important materials. These traditions of self-sufficiency have some advantages, not least in providing working scientists with a sense of the economic cost of laboratory supplies that might otherwise be taken for granted. But the diversion of creative people's time and energy to the simplest of laboratory tasks is a serious waste. Chinese who have spent time overseas are constantly remarking that their counterparts elsewhere can order supplies by telephone, and often expect them to be delivered the following day. Often, it seems easier for a Chinese laboratory to order an expensive piece of equipment from a foreign company (because the provision of funds for advanced equipment has been generous almost to a fault) than to spend a fraction of the cost buying goods and services within China.

The ever-present influence of the Communist Party is, on balance, another brake on effectiveness. But the issue is neither black and white nor immediate, as it may seem, from the West, it is bound to be. China's traditional respect for scholarship has ensured that the heads of institutions are invariably able people. The notion that for every such person there should be a party secretary, usually full-time, whose constituency consists in principle of the whole institution, but whose criteria for deciding what should be done may be qualitatively different, would seem a recipe for continual disaster. The Cultural Revolution shows that disasters on a national scale can happen. But for the present, the chief influence of the institutional party seems generally supportive of what the managers seek to do. So long as the cry is that science must do more to make China's industry prosperous, and while research directors share that aim, there is unlikely to be trouble. It is naturally impossible to tell how often original lines of enquiry are stifled by this unfamiliar consensus.

Survival

Against this background, perhaps the most remarkable feature of the research enterprise in China is that it has somehow been able to survive. Where else could half of a country's research workers have been compelled to work as manual labourers (or worse, imprisoned or simply killed) for between four and six years and then be able to return to pick up the threads of their old projects? It may be true that much of the research at China's research institutes and university departments consists of an attempt to replicate what has already been done elsewhere, but it also often has a distinctively Chinese flavour. People are anxious to learn other people's techniques, but the problems they intend to solve are their own. The success, at a host of China's laboratories, in identifying the active principles of traditional Chinese medicines, and the way in which the Institute of Genetics at Beijing has used the techniques of meristem culture to improve and propagate crop species not tackled elsewhere, should be a proof of that.

In any case, if shortcomings persist, they are now to be removed by means of the reforms decreed in March (see p. 222). That, at least, is what the officials in Beijing would like to think. In future, researchers will be able to succeed either by winning grants for the support of their research from a National Science Foundation still to be set up or by engaging in some kind of industrial activity. (Contract work for industrial enterprises will be commonplace; the search for innovations with industrial potential will be the more daring course, but sometimes people will turn their laboratories into factories.) Those who do not succeed in either course will keep their posts, their salaries and their apartments, but will be subjected to social pressure to do something, which is one of the ways in which the Party may help. So will this not powerfully contribute to China's goals?

Yes, but also perhaps no. That the new arrangements will increase the interest of researchers in China's industry is certain, but there is at least some cause to fear that China's industry may be so short of technicians and technically trained managers that the intervention of more researchers from academic institutions

may be an embarrassment. As things are, the proportion of young people entering higher education is about three per cent. Nobody will be surprised that there are too few engineers, and it is wise that the next five-year plan (to begin in January) should allow for more expansion of technical than of university education. But it will also be a surprise if, ten years or so from now, the then Chinese government is not bewailing the folly of its predecessors in neglecting the rapid expansion of higher education. China has done wonders in the past three decades, by making more than 90 per cent of its population literate: should it now adopt the goal of bringing out the full potential of that literate population? The government may have underestimated the scale on which higher education needs to grow.

Research

It may also have underestimated the importance of basic research to developing China. To be sure, the government is busy with high-energy physics and with space research. But much of China's interest to the outside world, and capacity to win its collaboration, rests on the high quality and the distinctive flavour of what is best in China's research laboratories. Natural cleverness helps. The tradition which China's science has recently cultivated of setting itself impossible goals and then attaining them (the synthesis of insulin is the best-known example) is potentially stimulating for the rest of us.

There are several jokers in this pack of cards. The contrast between mainland China and Hong Kong is not the consequence of an historical accident, but is a sign of what difficulties the slowly waking mediaeval state will have to face in a very few years. The mainland Chinese who now comply with regulations about where they may choose to live, or how many children they may have, are the same Chinese who have made a scattering of improbable islands into one of the richest manufactories in the world. When the mainland Marxists shake their heads over the objective realities of the Marxist dogma, they are talking theoretically; what will they do faced with the contrast between Chinese peoples' inclinations and their system?

Overseas relations are also important. China for the past decade has revered the United States and, by extension, the rest of the West. Now there is a grudging recognition that Japan is passably a success. In the end, it seems more probable that China will turn eastwards, not just to Japan but to the Pacific as a whole. But what if it made common cause with India, another continent from which it is divided by its common character — a huge and diverse population in the fertile sub-tropics, a gulf between the peasants and the rest, a sense of antiquity?

So how should the outside world respond to what is happening in China? The urgent need for training for young scientists has been acknowledged and partly met, but more generosity would be seemly, even prudent. A greater interest in what is happening in Chinese science would be worthwhile in itself, but would also help to strengthen China's self-respect. Too many of China's journals go unread. More visitors not so afflicted by culture-shock that they can say what is wrong in what they see would be welcome, if only as a mark of the adulthood of China's science.

For China, the immediate problems are economic and political. The need not to grow more than twice as fast as the rest of the world seems to have been appreciated. Whether China will be able to achieve the goal of being as prosperous as the West while retaining its communist ideals is both an economic question (what kinds of incentives will be how generally spread?) and, obviously, a political question. Technically, and by its talent, China's research community could easily provide what the government expects of it. Not only China's technical community, but the rest of us, have a vital interest in knowing how the economic and political questions are resolved.

This survey has been written by Alun Anderson and John Maddox, whose visits to China in July and September respectively were arranged by the Chinese Academy of Sciences (Academia Sinica). *Nature* is grateful to the academy, and to the directors and staffs of many of its institutes for their help. [

How China runs its science

A long chain of command

At the very top of the pyramid of organizations involved in science and technology comes the **Science and Technology Leading Group of the State Council**; essentially a group of members of the State Council with a special interest in science and the power to push important measures through. The State Council is the highest body concerned with the day-to-day running of the nation — it is the equivalent of the Cabinet in a Western country and is supervised by the Standing Committee of the National People's Congress. Members of the National People's Congress — the highest representative body — are elected every five years and in turn elect the Standing Committee and the Head of State, currently Li Xiannian.

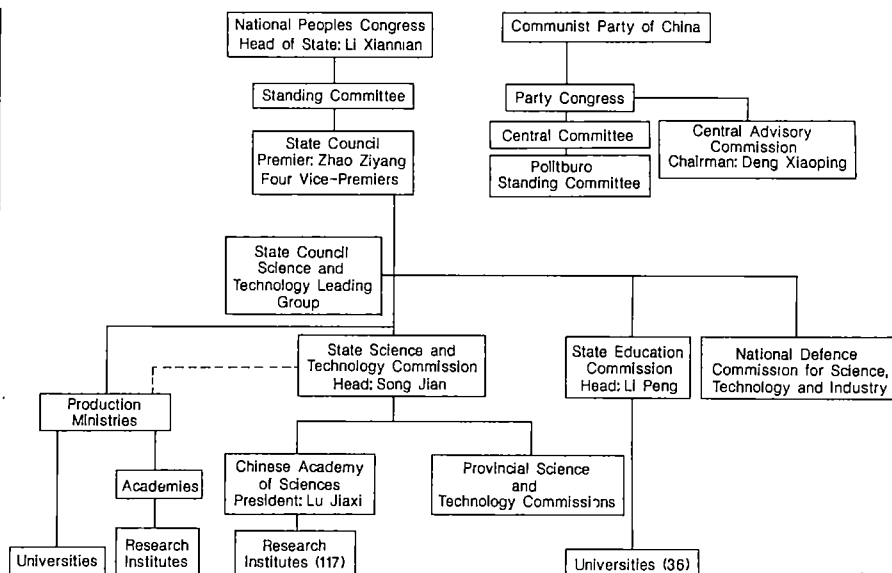

Although the State Council supervises all the ministries and agencies, as well as the People's Liberation Army through the Ministry of National Defence, it does not lay down fundamental policy. That job lies with the largest political party, the Communist Party of China (CPC), and in particular with the Standing Committee of the Politburo of the CPC. Almost 40 million people are members of the party, membership requiring, among other things, a willingness to dedicate a great deal of one's spare time to Party work. But the CPC is not China's only party. Eight others exist although they lack any real power.

Members of the State Council are frequently also members of the Standing Committee of the Politburo and, of course, most of those elected to the National People's Congress are members of the CPC. Not all Politburo members hold state office; Deng Xiaoping, the most powerful man in China, does not.

Immediately under the State Council comes the **State Science and Technology Commission (SSTC)** with responsibility for formulating and implementing science and technology policy within the guidelines given by the State Council. Overall planning and financial support are worked out in cooperation with the State Planning Commission and the State Economic Commission.

Under SSTC supervision but with a great measure of independence comes the **Chinese Academy of Sciences**, whose 117 research institutes carry out the bulk of China's basic research and are well known to academic visitors from the West.

Also under direct control of the State Council are the various ministries. One, the Ministry of Education, became the **State Education Commission (SEC)** in June of this year, a jump in status which reflects important policy decisions on education. Attached to the SEC are 36 universities including many of the most

prestigious "key" universities. But there are many universities which do not belong to the SEC but are attached to individual **production ministries**, for example, the Ministry of Petroleum has five universities.

In total, the number of ministries is very large by Western standards. Even though reforms in 1983 halved the number of high-level government bodies, there are still 33 ministries and 6 commissions (as against just 12 ministries in Japan). Just why there are so many is easy to understand when it is remembered that all the means of production are owned by the state. To administer and plan their activities a whole set of industrial ministries is required: aviation, chemicals, coal, machine building, metallurgical industry, nuclear industry, space, textiles and so on, just as in the Soviet Union. Many of these ministries have their own schools as well as universities; they may have their own farms and own factories supplying consumer goods for their workers. Each ministry is thus semi-autonomous.

Some ministries also have their own research **academies**; best known are the **Chinese Academy of Medicine** under the Ministry of Public Health and the **Chinese**

Academy of Agricultural Sciences under the Ministry of Agriculture, Animal Husbandry and Fishery. Each academy in turn runs several research institutes. Individual factories and state enterprises supervised by the various ministries also maintain research laboratories, some of them large.

At the provincial and municipal level of government, much of the above pattern is repeated on a smaller scale. A **Regional State Science and Technology Commission** coordinates local research efforts and bureaus of the local government which match the central ministries look after local industry and solve their technical problems through small research institutes.

Almost all basic research is carried out by the big national institutes: the Chinese Academy of Sciences, the "key" universities, and the academies belonging to ministries.

The large number of scientific societies in China is coordinated by the **China Association of Science and Technology (CAST)**, an organization of growing importance not only in arranging academic meetings and international exchange but in its educational activities and in the expert advice it gives to state bodies. □

The new reforms

Pragmatism now the watchword

DRAMATIC changes are taking place in the organization of science and technology in China. The changes will affect all scientists, in the universities, research institutes and in industry, and will reward those institutes and individuals that contribute to China's scientific and technological development.

This development is no surprise. The reforms are themselves a reflection of the huge changes in social and economic life that have taken place under the pragmatic leadership of Deng Xiaoping. The reform began in China with the smashing of the Gang of Four and Deng's return to power in August 1977. By 1982 and the 12th Par-

ty Congress, he and his supporters were in complete control and the rhetoric and personality cult of Chairman Mao and his successor, "Wise Leader Hua", had been cast aside.

National goals now seem to have less to do with ideology than with making rapid material progress. The primary aim, set by the 12th National Congress, is to "quadruple the gross annual value of China's industrial and agricultural output by the end of this century and then proceed to raise, within the first 30–50 years of the next century, China's economy close to the level of the developed countries".

To achieve these goals, Deng has trans-

Individual responsibility taking over from egalitarianism?

THE "responsibility system", which has lately given Chinese peasants the right to sell food crops for what they can make in the free markets, also applies to the research enterprise, but in ways that seem to vary in a bewildering fashion from one institution to another. This is why the State Council's Leading Group on Science and Technology is even now drafting regulations to determine what should happen to the financial rewards of greater collaboration with industry. Wu Mingyu, vice-chairman of the State Science and Technology Commission, hopes that the rules will be ready by 1986.

At present, the practice is that a sizeable proportion (usually a half) of the money received under industrial contracts is passed on to the parent organization, the Chinese Academy of Sciences or the Commission on Education. It also seems that individuals can receive between 5 and 8 per cent of the income earned from industry by way of higher salaries, although these awards will certainly be shared by the whole of the research group concerned, perhaps the whole of a department and sometimes even by the whole staff of an institution.

Thus at the chemistry department of the University of Beijing, 30 per cent of outside income is handed over to the university and

rather more than 40 per cent goes on further development (which means research equipment and consumables). Personal awards amount to less than 10 per cent of the total, and are shared out among the whole of the department's staff *pro rata* with salary.

There is some chagrin at the high rate of tax on such payments. Annual supplements of less than three months' salary are paid gross, but if the amount of a person's extra payment should be 6 months' salary, the department is required to pay over three times as much to the state, thus sharply reducing the total available for awards.

At the Academy's Institute of Microbiology, the practice is different. Outside income is shared equally with the Academy, while 30 per cent of the receipts is used to cover research costs (so reducing the recurrent cost to the Academy). Between 5 and 8 per cent of the institute's share (roughly 500,000 yuan last year) can be used for making awards to individuals responsible for the research concerned, while the remainder is spent on project-related research.

Elsewhere, the novelty of the notion that research can spell money means that for the time being much more informal arrangements obtain. At the Institute of

Electronics at Guangzhou, which has just sold the software for a word processor program for manipulating Chinese characters to a Hong Kong company, for example, the local branch of the Academy seems not yet to have learned about the contract, and thus has not had a chance to say what should be done with the HK\$ 100,000 the institute now has sitting in the bank.

The rules now being drafted are likely to endow these arrangements, themselves quite novel, with a degree of formality. Wu Mingyu says there is a case for treating institutions differently according to the balance of their research, basic or applied. The obvious difficulty is that under the system to be introduced in 1986, when basic researchers will be expected to compete for support by means of formal applications to the National Science Foundation (see p. 210), the pattern of financial pressure will still leave even the best basic researchers with the knowledge that they would be financially better off working on a contract for an enterprise of some kind.

The obvious resolution of the difficulty would be to include salary supplements in grant awards. It will be interesting to see whether the leading group decides that some such solution, however inequalitarian, would be in China's best interests. As things are, it seems, anything is possible. □

formed Chinese life: the door has been opened to the West to encourage foreign investment; market forces, not central planners, are to determine the pattern of industrial production; peasants are allowed to farm their own land and to sell their surplus produce at free markets; and intellectuals and scientists have been given back their high status but not yet salaries to match. At the same time, many leftists who were promoted during the Cultural Revolution are being removed from office; the Peoples' Liberation Army is being severely reduced in size.

But the path to reform has not been uniformly smooth. In September, at a national conference of the Chinese Communist Party convened exceptionally between party congresses, Deng had to pay a high political price for his latest triumph, the replacement of more than sixty ageing members of the Central Committee by younger people, some of them conspicuously Deng protégés. For one thing, he found it necessary to emphasize in his own speech to the conference that reform should not be allowed to jeopardize Marxist principles, while the delegates also heard a sombre warning from another member of the Politbureau, the veteran Chen Yun, that the opening of China to the outside world, necessary though it may be on economic grounds, entails the risk of "corrosion by decadent capitalist ideology and conduct". Chen's speech was widely regarded in September as a demand that the reformers should be

more alert to the dangers of the course on which they had embarked.

In his capacity as first secretary of the Central Commission for Discipline Inspection (an organ mirrored at all levels of Chinese party society), Chen went on to demand that the Party should be "vigilant" in the fight against lawlessness, corruption and pornography. The "bourgeois decadent ideology of putting money above all is corrupting party conduct and social conduct in general", Chen said.

This is one sign that opposition to the process of reform, although now largely silenced, has not entirely vanished. Now, it is as if the process of reform itself is on trial. Its successes have been spectacular, especially in the countryside, but there have also been problems galore. The official statistics show that China is now entering its fifth consecutive year of growth at ten per cent a year or more, which is amply reflected both in the construction sites being worked in all the cities and by ordinary people's interest in consumer goods (refrigerators for the time being the most sought after). The other side of this coin is that imports are growing faster than exports, while many of the new projects on which the reformers have embarked have come to grief. These are now some of the reasons why the outline of the next five-year plan (1986-90), also agreed at September's national party conference, offers the more modest target of 7-8 per cent a year — twice the present rate of growth in Western Europe and still

enough to reach the target of quadrupled production by the end of the century.

On a more human scale, new opportunities for people to make money have led to some spectacular cases of corruption, even involving Party members. Some changes have had to be undone abruptly. Thus, in 1984, fourteen coastal cities were declared special economic zones, free ports of a kind in which foreign investment would be encouraged and in which, it was intended, joint enterprises between Chinese and overseas companies would flourish. By July this year, however, all but four of the economic zones had been closed, partly because they had not attracted suitable investment, partly because of the fear that corruption would get out of hand.

Inevitably, the rapid growth of the past five years has brought great inequalities. Perhaps for the first time in Chinese history, there are people in the cities who envy the peasants. The official response that "some must get rich first" does little to ease the tensions that have built up.

When the new pragmatic policies first surfaced in 1977, science and technology were seen as a force that could transform China. Soon science was to obtain a place of honour among the "Four Modernizations" (science, agriculture, industry and defence). And after years of being reviled among Mao's "stinking elements" (including landlords, capitalists and counter-revolutionaries), scientists and intellectuals suddenly became respectable again.

In 1978, Deng announced that "intellectuals are part of the working class", professional titles were restored and academic societies allowed to function again. In the euphoria of this "Springtime for Science" it was not surprising that over-optimistic plans were laid.

At the 1978 National Science Congress which confirmed the restoration of science, huge programmes were outlined in eight areas: agriculture, energy, materials science, computer science, lasers, space, high-energy physics and genetic engineering; and plans were included for a 50-GeV proton synchrotron and a fusion machine on the same scale as the Joint European Torus (JET). But within a few years, the limits of what could be achieved were realized, and attempts to aim straight for high technology were modified. On 13 March 1985, a new and thoroughly pragmatic series of reforms were announced by the "Decision of the Central Committee of the Communist Party of China" after some years of discussion with scientists.

The essence of the reform, entirely in line with general policy, is that "science and technology must be oriented to economic reconstruction". To that end, "the defect of relying on purely administrative means in science and technology management, with the state undertaking too much and exercising too rigid a control" must be remedied. The plan says that while research projects of national priority should remain under the control of the state, other activities conducted by the scientific and technological institutes are to be managed by means of "economic levers and market regulation". In other words, many scientific institutions and scientists are going to have to find customers to pay for their work. Many defects of the present system are frankly described in the decision document, and the ways they are to be remedied are made clear.

First, the system of the "great iron pot" is to be eliminated. Hitherto, the huge numbers of research institutes attached in one way or another to the government have yearly been doled out fixed sums of money for their services, largely calculated according to staff numbers. The key projects on which they are to work have also been determined by the government and allocated to institutes deemed suitable to carry them out. The result has been research institutes that are isolated not only from industry but also from one another, under little pressure to deliver results, and seriously overmanned.

Under the new regime, state handouts for research are gradually to be withdrawn. Instead, institutes are to "earn income and accumulate funds" by contracts, by transferring research achievements (to industry), operating joint venture and export (companies), and consultancy. The experiment has already begun. Some research institutes have seen their state income cut; soon the system will spread nationwide. The Party expects that some

institutes will not survive in the new competitive atmosphere and will have to close. Others may find it expedient to merge with related institutes or even with industrial organizations. All institutional innovations, it seems, will be encouraged.

Institutes carrying out basic research will come under a different kind of pressure. It is accepted by the Party that basic research must continue and that financial support cannot come from industry. But the costs of basic research (over and above the salary costs of those responsible) will no longer be provided automatically with the public subvention for an institute. Instead, there is to be a system of competitive grants open to all scientists in China, not only those who work in formal research institutes.

A start has been made on the development of such a system within the Chinese Academy of Sciences, which has set up a small science foundation to receive grant applications for researchers at its own institutes. These are subject to peer review, as elsewhere. Next year, according to the plans now laid, there will be a National Science Foundation for whose funds scientists from universities will be able to compete on an equal footing with those at research institutes operated by the production ministries and provincial governments as well as by the Academy.

As recently as early October this year, the constitution of the new foundation had not been finally settled, although there is every likelihood that the State Science and Technology Commission will have formal charge of it. But officials say that the chairman of the foundation will have to be an independent person. The scale on which the foundation will operate is similarly undecided, although it seems clear that an annual budget of less than several hundreds of millions of yuan a year will mean a cut in basic research support.

The new system will have radical consequences for the ways in which individual laboratories function. In many of them, people whose work can attract support from industry will be working alongside those who must look to the National Science Foundation for help with research costs. Even when grant applications succeed, basic researchers will not be entitled to the salary supplements that those working on applied research projects may in future enjoy when industrial innovations are taken up and exploited by industry.

Some fields will continue to be supported differently. Research institutes involved in medicine, public health, family planning, disaster prevention, meteorology and so on will continue to be supported by annual grants, but the plan is that the institutes will in future make proposals indicating which projects they wish to carry out. This is a departure from the present system, under which projects have been allocated from on high.

To get the institutes in shape for the new competitive world, they will be given con-

siderable decision-making powers of their own. During the Cultural Revolution, research institutes were run by "revolutionary committees" dominated by Party officials; ideology took precedence over scientific goals. Now, the power of scientific directors is being restored. Party officials are "to help with the effective application of the system under which directors assume overall responsibility and promote scientific and technical development". Indeed, a prerequisite for a Party committee secretary is now that he or she should "possess a certain level of scientific knowledge and be keen on scientific and technical undertakings and conscientious in carrying out the Party's policy towards intellectuals", a far cry from the days of the Cultural Revolution. Directors will thus now be firmly responsible for the scientific direction of their institutes and can, in principle, even sack inefficient workers.

There is also to be more freedom and greater rewards for the individual scientists. They will be allowed to do part-time consulting work and to keep the money they receive from it (minus any sums due for the use of state facilities). Large rewards are to be made to the individual scientist (rather than the institute) for major achievements (although there may well be pressure to share any such rewards out). And hitting at one of the most intractable problems of the present system, "rational job mobility" is to be introduced for "competent people must no longer be made to sit idle and waste their talent".

How far this reform will go remains to be seen; there are already semi-official newspapers in circulation offering job appointments; some show a huge range of perks for those willing to take their skills to organizations outside the big cities. But the present system of allocation to one's place of work upon graduation is still far from anything like an open job market.

What are the chances that the reforms can be put into practice? Accounts of how individual research institutes and universities are coping will be found in the pages that follow: the pace is faster in some than others, and some new kinds of profit-seeking technology corporations, unthinkable a few years ago, have sprung up. But China is a vast and bureaucratic country and changes at the lower levels of the hierarchy do not automatically follow central directives at any speed.

A story is already in circulation of a scientific director of a small and distant research institute who found, despite Party directives, that he could not wrench control over research from the local Party man. In the end he travelled to Beijing, appealed to Party authorities and returned with a high official who made it clear that the Party line was to be followed. No doubt change will be resisted at many levels by many different forces: at this early stage it is hard to guess what will emerge in the next year or two as the reforms take effect. □

Science policy

Low versus high technology

OVERALL responsibility for China's science and technology policy rests with the State Science and Technology Commission (SSTC). Like every organization associated with science, its fortunes have changed with the times: it was set up in 1958 during the Great Leap Forward, abolished at the start of the Cultural Revolution, and re-established in 1977 after the fall of the Gang of Four.

Since then the influence of the SSTC has gradually increased, at first under the leadership of Fang Yi, a very experienced politician and member of the Politburo. He did much to establish the SSTC's political respectability, but although he was college educated (unusual in the upper ranks of the Party), he had never been a research scientist. Now, the job of director general has gone to someone with a weighty scientific reputation: Song Jian, a 53-year-old cyberneticist, who trained in the Soviet Union, studied in the United States and took a leading role in the successful development of the space industry.

Most of the SSTC's departments are concerned with national policy, planning and legislation in science and technology. One of them, that for science and technology policy, effectively acts as a think tank for the Science and Technology Leading Group, the group of senior politicians in the State Council with special responsibility for making sure science policy matters receive top priority. And the SSTC also exercises ultimate control over the Chinese Academy of Sciences and ensures that government policy is carried out in a coordinated manner at other research facilities.

The SSTC does not itself maintain any experimental research facilities. Nor does it control directly the major part of the science budget. But it can combine the use of its own funds with the influence it has over allocations arrived at by the State Planning Commission (and given out by the Ministry of Finance) to provide effective control.

What this process has meant until now is the SSTC sitting down with the various science-related ministries and deciding on key projects of national importance that need special promotion — like those for

the development of the Yellow Loess Plateau, and fish aquaculture, for example — and then giving guidelines for how the funds should be allocated by the Ministry of Finance (on top of any routine allocations) as well as giving out the part of the budget it controls directly.

With the new reforms, much of this will change. The commission will still come up with key projects, but, as Lin Zixin, secretary-general of the SSTC put it, "instead of us selecting, we would like to let bids come from research organizations. Research, even on key projects would then be carried out under contract". Experiments are just beginning to be made with this new system, and if it turns out to be successful, then inefficient research organizations, unable to gain funds, will wither away. To sum up, "we used to choose from the top, the new plan is to be the reverse"; and at the same time, the new National Science Foundation will "cover a portion of basic research and applied research that can't produce practical economic results quickly".

This pragmatic approach comes along with a re-evaluation of what China can really achieve. Back in the heady days of 1978 many people were ready to believe that China could leap straight into an era of high-technology and catch up with the West.

Indeed, there are plenty of areas where China has done extraordinarily well: the manufacture of satellites, H-bombs and high-power electric generators are no mean technological achievements. The problem is that basic items such as bicycles, sewing machines and radio sets are of low-quality. Now there is an awareness that success in a few areas of high technology does not automatically feed into everyday products. Thus the SSTC has laid down five clear principles:

- to develop technology coordinately with society so that society can absorb its fruits and provide for its support;
- emphasize production technology;
- develop new technology in the industrial enterprises;
- in basic research stress China's unique problems;
- increase international cooperation.

These principles may sound unsurprising but they represent radical breaks with the past. Emphasis on research inside enterprises is a clear rejection of the Soviet model — independent state-controlled research institutes — which has been followed since 1949; instead it is now Japan, whose companies perform their own research, that provides inspiration. And emphasis on international cooperation is a complete break with the view held during the Cultural Revolution that "learning from abroad is a betrayal".

One problem still to be tackled is how to

get sufficient talent into industry — it will mean countering the prestige of the Chinese Academy of Sciences, for one thing. As Lin put it, "we have never paid enough attention to the needs of the enterprises, the best graduates were allocated to the institutes and government agencies. Although there is no difference in pay between factories and academia, people feel they are at a lower level if allocated to a small factory. This is a complex social problem which is very difficult to change". But the carrot of financial incentives for those who work in industry is not yet under consideration.

It is clear that there is still debate over what technological level China should be trying for with some still believing that the "highest" technology is the best technology. Lin holds the view that it is selecting appropriate technology that is important. For example, in 1978 Chairman Hua

The State Science and Technology Commission's headquarters.

announced that 85 per cent of agriculture would be mechanized by 1988 — not a prediction that will be fulfilled. But Lin now argues that the use of draught animals and manual labour is actually much more rational; it should not be thought of as a sign of backwardness.

The planning of basic research is largely to be left to the Academy. But there will be some emphasis on solving problems specific to China. One example is research on rare earth elements in which China is particularly rich, and on which much basic research in refining remains to be done.

But whatever policy decisions are made there remains the awareness that shortage of technical skills, more than anything else, will determine the pace at which technological progress can take place. There are, according to the SSTC, 1.6 million enterprises in China but only 1.8 million "technical" staff who have received post middle-school training. In the electronics industry only 20 per cent of staff is trained, in the iron and steel industry 10 per cent, and in textiles and light industry 1 per cent. It is boosting these figures that will have to receive the highest priority of all. □

Lin Zixin, secretary general of the State Science and Technology Commission.

Academy of Sciences

A pawn in revolutionary history

THE history of the Chinese Academy of Sciences is a mirror to the history of New China; for better or for worse, each change in policy has affected the Academy's fortunes. The organization was founded in November 1949, just one month after Mao Zedong proclaimed the founding of the People's Republic in Tiananmen Square. First priorities were to build an effective scientific research community; the Academy began with just twenty institutes and 300 research staff inherited from pre-revolutionary days. A major source of help was scientists who returned from overseas inspired by the desire to help China's development. A new science press was soon established and a major library; branches of the Academy were built up throughout China and academic relations with foreign countries — mainly in the Eastern bloc — were established.

In this early period China astonished the world by the moderation of its policies. Land was redistributed to the peasants and factories gradually nationalized, with compensation paid to the owners, giving China the highest growth rate in Asia.

In 1956 enthusiasm for science intensified when Mao Zedong called for science to lead the country forward and gave freedom to intellectual enquiry with the famous slogan "Let a hundred flowers bloom, let a hundred schools of thought contend". A 12-year science plan was also made with emphasis on natural resource exploration and on catching up with the West in key technologies — atomic energy, semiconductors and jet aircraft. All this helped to generate enthusiasm for science among the people.

But that enthusiasm was soon to get out of hand. In 1958 the Great Leap Forward began. Mass enthusiasm for science led to wild optimism about what it and China could achieve. The slogan was "Catch up with the USA, overtake Britain". As revolutionary fervour was intensified by mass campaigns, millions of peasants were reorganized into huge communes, massive irrigation projects begun, and dams built. The effects were felt in the laboratories; normal work ended, wild claims were made for all sorts of fantastic inventions and many people spent their time trying to put into effect the revolutionary sayings of the Chairman rather than doing research. In some laboratories the "backyard blastfurnaces" that Mao had claimed would allow rapid modernization were set up. And those who had spoken out during the "hundred flowers" period now found themselves under attack as rightists. Overall there were some gains for science in the enthusiasm for it which spread among the people, but the disruption prevented any real progress being made.

The dominance of the radicals ended as the Great Leap Forward ground to a halt in a morass of inefficiency compounded by some of the worst natural disasters China had experienced for a century.

In 1961 many tens of thousands of peasants starved to death in the countryside. And the year before, China had finally broken with the Soviet Union over the latter's "revisionist" policies and "friendship" with the United States, resulting in withdrawal of all technical advisors.

These disasters were quickly followed by a swing from the radical to more pragmatic policies. Mao Zedong lost his post as Head of State to Liu Shaoqi and Deng Xiaoping — now the most powerful man in China — became Secretary-General of the Party. These two, along with Premier Zhou Enlai did much to undo the worst aspects of the Great Leap Forward; some private plots of land and financial incentives were introduced in order to improve efficiency.

For the Academy it was a period when the role of scientists was made clearer. Guarantees were given that scientists could spend five out of six days in their laboratories (instead of at political classes); gone was the time spent on writing poems to praise Mao, practising in the militia, performing manual labour along with the peasants and all the other things that participation in mass movements had required. Also it had become clear after almost ten years of turmoil that there simply was not enough food for the Chinese people. Agricultural research now proceeded at top speed and real gains in food output were made. By 1964, science was flourishing as never before. In 1965 the Academy succeeded in launching a satellite, the world's first chemical synthesis of insulin was completed at the Shanghai Institute of Biochemistry and major advances were made in atomic energy research. But then the Great Proletarian Cultural Revolution began.

For some years leftists associated with Mao Zedong had been attempting to regain power through a Socialist Education Movement intended to mobilize the peasants to greater revolutionary ardour. Then in July 1966, after more than a year in which he had made no public appearances, Chairman Mao, then 73 years old, was seen in television pictures broadcast worldwide taking a "ten-mile" swim in the Yangtse river. The next month the Red Guards appeared in strength. Deng Xiaoping and Liu Shaoqi fell from power, the latter to be branded a "renegade, traitor and scab" and to die in disgrace. Deng spent two years in solitary confinement before being exiled to Jiangxi Province.

The ten years that were to follow were

Leading light in lasers

ONE of China's laser researchers remarked that there are more people studying lasers in China than in the rest of the world put together. Although said with a laugh it might even be true; one problem in China is that too many scientists cluster around a fashionable topic (a phenomenon dubbed the "swarming of bees") and then, because institutes are isolated from one another, proceed to duplicate low-level research being done elsewhere.

The Academy's Shanghai Institute of Optics and Fine Mechanics is not among those doing low-level research; it is at the top of the laser tree. It is not actually in Shanghai but in Jiading, more than an hour's drive out in the country where it was built in 1964 as the first part of a science city. The Cultural Revolution then came along however and the city was never completed.

The institute now has 600 researchers, 500 technicians and administrators and some worthy achievements. Among them are the development of inertial confinement fusion systems, a three million joule per pulse high-energy laser, and excimer lasers. Basic research at levels no different from that in the West is going on in laser

Professors Fang Honglie, Bi Wuji and Wang Kewu (left to right) stand in front of the target chamber for their six-beam, 10-watt a pulse, inertial confinement fusion research machine.

spectroscopy and atomic hyperfine structure. But even so the institute is under strong pressure to earn its own keep.

This year its funds were cut by 23 per cent and further annual cuts of 20 per cent are expected. The institute has reacted in two ways. First, industrial contracts are being sought and manufacturing facilities established. Fortunately the institute grows very good Nd laser rod glass as well as Yag, which has already been exported to Australia. Other commercial possibilities lie in laser writing of integrated circuit masks and medicine. Second, the institute is seeking "open" status: extra funds will be received from central government to allow scientists from all over China to come and run experiments, in a scheme administered by a national committee. And of course, institute scientists will be applying for funds from the new Science Foundation. □

Academy's computer centre really means business

THE "Technology Service Corporation of the Computing Centre of the Chinese Academy of Sciences" could do with a new title, as its general manager Yi Hui-en readily agrees. For far from being some sub-section of a research institute, the corporation is really a "high-tech venture business" of a kind unimaginable in the China of a few years ago.

The corporation began life in the summer of 1981 after the policy shift to a "commodity-based" economy was announced. Its aim was to train technicians who would then liaise with scientists in the Academy's research institutes and then help turn results into marketable products. Initial capital — just 50,000 yuan — came from the Academy. Senior middle-school graduates were provided to staff it, for at that stage an allocation of university graduates could not be obtained.

Despite these rather unpromising beginnings, the corporation has since generated 5 million yuan in profits and long ago paid off its loan. Now, not a single yuan is received from the state; everything including operating expenses and salaries is paid out of profits. And the profits ratio would make many a Western capitalist green with envy — last year profits of some 1.6 million yuan were achieved on a turnover of just

4.6 million yuan.

The corporation was one of the first of its kind in the field but there are now more than 200 similar organizations nationwide. All have the dual aim of "turning research results into productive forces" and "maintaining technological expertise, particularly through the training of technicians".

This particular corporation has made its money by catching onto the computer boom; others operate in fields as diverse as cell culture and new materials. Its biggest financial business is selling hardware, mostly small computers, but many of its 170 staff are designing software packages. It has set up a joint software venture with a Japanese company, is operating five factories in the Special Economic Zone bordering Hong Kong where a micro-computer is assembled for a US company and is also manufacturing automation control devices (programmable counting devices and the like). Now it is diversifying with a factory to produce vitamin oil by a method developed in Academy institutes in Hefei.

The corporation's staff claim they have complete freedom to launch new projects and choose new areas to explore. Ideas come from its own "think tank" containing scientists and engineers from various insti-

tutes. It is not restricted to working only with the Academy and links are formed with any research institute that might be able to contribute a marketable product. Diverse links are thus possible and it is hoped that more joint ventures will be launched with foreign countries. Now the corporation is a success, university-trained staff are being allocated to it for further training, and it may also be given the right to confer higher degrees.

Right now the only obstacle to further growth is lack of capital. But these are perhaps the golden days. The market is still firmly in the sellers' hands — such is the shortage of expertise that the corporation never needs to go out of its way to advertise its wares. But the prospect of growing competition for customers with other corporations is on the horizon.

Where then will be the boundary between communism and capitalism? No specific answer seems to exist. Perhaps the best that can be done is to quote Manager Qiao, a fictional character whose adventures were serialized in the *Workers' Daily* a few years ago. "Of course", Manager Qiao says "competition between factories in China will be totally different from the cut-throat struggle in capitalist countries. . . we can't scrap socialist cooperation". □

the worst period for science and technology. At the outbreak of the Cultural Revolution the Academy had 106 institutes, by 1973 the number had fallen to 53. Some were simply closed altogether, others were taken over by regional authorities and others packed up and moved far into remote regions of China. Research staff had stood at 60,000 in 1965; by 1973 only one-third were left. Some 30,000 scientists were sent for re-education in "cardre schools" in the countryside. Those who were simply given physical labour in the country were lucky; in some institutes more than half the staff died as attacks on any kind of intellectuals intensified. In one institute a political appointee claimed that "knowledge of a foreign language" was sufficient evidence of being "a foreign spy".

But the terrible sufferings undergone by scientists and intellectuals during the Cultural Revolution are already well known. Mention of these days is now almost always greeted with laughter — not because there is anything funny to recall but because a laugh is a standard Chinese response to a memory that is too painful or too embarrassing to talk about.

The Cultural Revolution proper lasted only until 1968, for by then the activities of the Red Guard had grown so uncontrollable that industrial production was being disrupted. The People's Liberation Army, headed by Lin Biao, restored order and sent millions of young people to work in the countryside and to establish communes in remote border regions. But the

persecution of intellectuals and domination by the left was not to end so quickly. In 1971 Lin Biao died in an "aeroplane crash" after a failed attempt to assassinate Mao Zedong. Only gradually, under the influence of Prime Minister Zhou Enlai, were things restored to something like normal. In 1973 Deng Xiaoping was once again given power.

His return was to be for a few short years in which there was not time to undo the harm of the Cultural Revolution. At the same time as his reappointment the "Gang of Four", headed by Mao's wife Jiang Qing, had launched a leftist campaign. Then in January Zhou Enlai died, removing the last remaining moderating influence upon the radicals. A few months later Deng Xiaoping was again dismissed from power. It was then that fate intervened — in September 1976 Mao Zedong died. Within weeks the Gang of Four were under arrest and the pragmatists were back in power. By August 1977 Deng Xiaoping was in high office for the third time.

Although the worst excesses of the "leftists" were over by 1973, very little progress was made in rebuilding the scientific framework between 1973 and 1977 while the leftists and the Gang of Four had influence. But after the "smashing of the Gang of Four" (a standard phrase in China, and one always enunciated with particular relish) progress was rapid.

In 1977 the "Four Modernizations" were announced as the key objectives for the nation: modernization of agriculture,

industry, defence and science and technology. A national science congress was convened in 1978 and a highly ambitious eight-year plan approved which would once more make science and technology a major force in the nation. Some of the more ambitious projects have since been abandoned or scaled down, as described elsewhere.

By 1985 the Chinese Academy of Sciences was in better shape than ever before, with 117 institutes and 80,000 staff. Almost half are technicians and scientists and the remainder administrators, support staff and Party workers. A huge support staff is necessary partly because the Academy has to manufacture much of its own equipment at its eight factories — it even produces its own gases for use in research laboratories as there is no national supply facility.

Institutes dispersed during the Cultural Revolution have in the main returned to their old homes; an exception is the Academy's university, the University of Science and Technology of China, which was moved to the small city of Hefei in Anhui Province. A science city has grown up around the university, including a number of new research institutes, and there is now no longer any possibility of moving it back to Beijing.

Like other institutions, the Chinese Academy of Sciences is now busy implementing the new reforms. Several unique moves have been taken to overcome the difficulties spelt out in the reform document. To answer the criticism that

institutes are too isolated, some, or some subsections of them, are to become "national" laboratories open to other research workers throughout China. The idea is that a part of the staff will not be fixed but will be appointed from other institutes on one- or two-year contracts. A national committee with representatives from many institutes will appoint the director of the new "open" laboratories. Seventeen institutes have already been chosen for the scheme: they include the Theoretical Physics Institute and the Institute of Mathematics. Many other institutes are also hoping to gain "open" sta-

tus, in part because funds will be provided by the central government which could help offset income lost as the reforms begin to take effect.

Another move which the Academy has been taking over the past few years is to establish new high-technology corporations which can market ideas developed in the Academy's institutes; one, described in the pages that follow, is principally concerned with selling hardware and developing software; others have spun off from botany into cell-culture technology, and from chemistry into the manufacture of new materials. □

Education commission and universities

Catching up the priority

EVER since the founding of the People's Republic, it has been the Chinese Academy of Sciences, not the universities, that has dominated the nation's basic scientific research. In terms of facilities, time available for research and funds the universities have been poor cousins to the Academy. But the new reforms and the rebirth of the Ministry of Education as the more powerful State Education Commission (SEC), are likely to give the universities a more equal chance.

Commission status was gained in the middle of June this year and in July, when a visit to the commission was made, the paint on the new signboard outside the building was scarcely dry. New policy decisions had not yet been made in any detail. One thing that was clear, though, was that the new head of the commission, Li Peng, is a powerful figure.

Li is one of the nation's four vice-presidents and holds a number of other ministerial appointments, including responsibility for energy. In September he was one of the "new generation" to be appointed as a member of the 24-man Politburo. Many believe he is on the way to the very top and at 57 he is still young in Chinese terms. Li is likely to be able to get things done and to be able to overcome bureaucratic resistance to some much needed reforms.

Why university researchers feel reform is necessary can be seen by a glance at the

table shown below.

Although the Academy takes a share of the state budget for natural sciences research many times larger than that taken by the SEC universities or universities attached to other ministries, it does not win the majority of State Science and Invention Prizes. Nor does it have a majority of highly qualified staff. Of course, neither of these measures can be said to unequivocally measure scientific ability, but the disparity in resources allocated to the universities and the Academy has been a source of friction for more than 30 years.

From next year, university scientists should get more of an equal chance to prove their worth. A National Science Foundation will be established in 1986 (although who will run it has yet to be settled by the State Council) and university researchers will then compete for grants with researchers from the Academy and elsewhere. They will also be able to bid for contracts for large research projects that would formally have been allocated by the government. The new foundation will probably have around 100 million yuan at its disposal for the first year, three times the funds of the present Academy foundation.

Bringing about changes of this kind will be just one task for the SCE, and a fairly minor one at that. More important is that the whole of higher education be managed

rationally. At present the SCE has 36 universities under its direct control, many of them "key" universities which attract the most funds and the best students. Other universities belong to other ministries; some of the best of these (for instance the University of Iron and Steel Technology of the Ministry of Metallurgical Industries) are managed jointly by the SCE and the relevant ministry, but most of them are exclusively managed by their own ministry. Graduates from these latter universities — or around 80 per cent of them — are sent to the parent ministry's offices, colleges and factories to work. Only the remainder may go elsewhere.

No-one feels that this divisive system is really for the best; but change is sought that goes beyond just making all universities answerable to the SCE. Instead, the Party wants to see a loosening of links between all universities and their ministries, including even the SCE; just as there should also be a loosening of links between factories and ministries. Indeed, going higher up the hierarchy, the Party would like to see many ministries done away with and turned into state corporations. A few years ago, that was what happened to the Ministry of Shipbuilding; it became the Shipbuilding Corporation to "overcome bureaucracy and to practise free competition".

How far reform can go in the case of the universities is hard to predict. Many academics are sceptical, one commenting that "it cannot be changed", but then adding "but maybe Li has the authority to do it".

Li will also have his hands full in simply trying to get the whole educational system close to world standards. In 1981, there were around 1.279 million students at China's universities, 1.061 million of them at four-year universities and the rest pursuing two-year courses. Now the total is close to two million. In the Philippines, however, with a population of just 48 million, there are 1.8 million university students. Things are certainly getting better and this year, half a million university places will be available for three million applicants, but there is still an enormous distance to go.

Further down the system problems are grave. Before university comes three years senior middle school, three years of junior middle school and six years of primary school. The goal being fought for at the moment is universal primary school education. Only wealthy Jiangsu Province has so far been successful. Nationwide, 94 per cent of children enter primary school, but only two-thirds complete the first six years of schooling, with drop-out rates very high in rural areas. The hope is that primary school attendance will be made compulsory by 1990. One problem is that education, even at the primary level, is not free and many peasants want their children at home working on the land. □

The natural sciences in China 1984

	SEC universities	Chinese Academy of Sciences	Other universities
Full and associate professors	10,765	2,956	26,299
Doctoral students	316	140	233
MSc. students	13,207	2,885	16,815
Science and Invention Prizes	163	152	112
Central government budget (million yuan)	20 (160)*	460	30

*Including funds from industry for research in natural sciences. The above figures do not include salaries or major capital expenditures.

Life as a student

THE exact conditions that students face at university vary from place to place: some have introduced Western features in their curriculum and assessment methods, others adhere to a Soviet model and a minority have not yet recovered from the effects of the Cultural Revolution. But political classes, which once dominated university life, are down to 72 hours a year in the key universities.

One constant factor seems to be that all students live on campus, generally six to eight to a dormitory with bunk beds and one long table and bench being the norm. At graduate level, more space is provided and students live two to three to a room.

At Qinghua University a US-style grade system has been adopted. Each term the available courses, teachers and hours of lectures are announced along with the number of credits that can be gained towards the total needed for a degree. The course is five years, rather than the usual four, and a final-year project is seen as of key importance. That project might be something like taking an old theatre and making a plan for its restoration. Once all that is completed, the student faces an oral exam: 20 minutes to describe the project and then 40 minutes to defend it under questioning from the staff.

Entry into graduate school is not, however, gained by obtaining a good degree. A quite separate nationwide examination is taken in the winter of the final year, with the results announced in April. The successful student does not have to stay on at the same university for graduate work but 70 per cent do so.

Those who do not go on to further studies will be assigned jobs on graduation. In the old days (just a few years ago), students had no choice over where they would be sent to work. But nowadays lists of jobs are usually circulated, with the best students given first choice. The lists are prepared by the State Planning Commission after meetings at provincial level to collect requests for the highly trained products of the key universities. Once a student has been appointed to a work place, he or she may have little chance of changing it. The system seems widely accepted by students (as is the extreme difficulty of obtaining permission to live in Beijing or any of the big cities) as being necessary for the "good of China"; but that does not stop people using every trick in the book to make sure it is someone else who is sent to a small factory, far from the capital.

Yet another examination awaits those who wish to go on from graduate school to a doctoral course. But those who do go through and complete the doctoral course are virtually assured of a lectureship: as doctoral courses began again only a few years ago, there are still only a few hundred with such qualifications in the whole country. □

University entrance

Cramming to join the elite

THIS year around half a million university places will be available; more than ever before. But with three million students likely to be taking the entrance examination, that still means tough competition, especially for entrance into the elite key universities.

For universities at the very top like Qinghua, Fudan and Beijing, successful applicants will need to achieve a score of somewhere around 455 out of 600 (76 per cent) in the six-paper, 100 marks a paper entrance examination. Papers can be taken in physics, chemistry, biology, history, geography, Chinese, English, mathematics (with separate papers for science and arts majors) — and everyone takes politics.

Other key universities might be content with some twenty marks less. That the dividing line is so thin shows how fierce the competition is at the top. Marks count for everything as it is not possible to conduct interviews.

There is plenty of competition further down the education system too. Differences in success rates between different middle schools are huge: some "key" and university-attached senior middle schools send almost all of their students to university while another senior middle school just down the road may be able to manage only 1 or 2 per cent.

As one father with a daughter studying for university put it "it would be hopeless to try to enter university from a non-key school". Getting into a key school is again largely a matter of passing exams, although "influence helps"; competition at 12–13 years is tough, with parents busy helping with homework until ten every

evening. There are even "key" primary schools with preferred entry to key middle schools (although steps are being taken to do away with them). All this hectic studying will be familiar to the Japanese, as will another new development, the appearance of after-hours cramming schools. More than a few schoolteachers now run special private classes for those anxious to succeed.

The present system is a far cry from the Gang of Four days when the "soldier-worker-peasant" students were sent to university on the recommendation of their workmates; in those days there were no examinations (and nor were there degrees or graduate students).

There is still a small percentage of students who do not have to go through the entrance examination. At Qinghua, for example, around five per cent are instead taken in on the direct recommendation of their schools. Recommendations are taken only from a few privileged "key" schools that have built up close links with the university and have a tradition of excellence. Students will need to have the school president certify that their ability, character and health are truly exceptional before they have a chance.

Under consideration is the highly controversial suggestion that entrance requirements should be slightly eased for those that are willing to pay university fees. Indeed, it is even possible that most students will be asked to pay their way through university. It is for the best, in the long run, some say. The logic — pragmatic enough — is that for every student who pays, an extra student can be taken on and total enrolment increased. □

One of the best of China's educational institutions — Beijing University. Situated in the northwest of the city, most of the university's buildings are in the traditional Chinese style. The pagoda in the background is actually a water tower supplying the campus.

Intellectuals

Jam tomorrow — perhaps

YOUNG lecturers now entering the universities face considerable frustration and, like all intellectuals, have to cope on salaries well below those of industrial workers.

All university promotion was frozen several years ago while the government tried to sort out a new personnel policy. On top of that, retirements are not taking place as planned. In theory, staff should retire at 60 (if male) or at 55 (if female). Associate professors may continue until 65, and professors to 70, but they are not supposed to have administrative responsibility. However, these rules are hardly ever enforced. The majority of full professors are in their seventies or eighties and associate professors in their fifties or sixties. Perhaps the example recently set at the Party Congress, where the older generation retired from high office *en masse*, will have an effect!

Many argue that the older scientists have to stay on because the generation that should replace them missed their education as a result of the Cultural Revolution. But there seems to be no shortage of younger talent: there are many in their forties waiting for promotion and some have talented postdoctoral researchers in "cold storage" on scholarships overseas.

Whatever happens, a young lecturer is

certainly not going to live in luxury. Wages are only around 90 yuan a month. To put that in perspective, the national average salary is now 95 yuan a month, so a university lecturer earns much less than a factory worker. Top professors can earn 250 yuan a month, and university presidents as much as 330 yuan a month. But recently, much to the envy of city dwellers, peasants near big cities who have been selling their wares in city free markets have been reaching incomes of 550 yuan a month!

Indeed, the new rich can be spotted in the Shanghai suburbs, driving into town in the morning in privately owned trucks (which bear distinctive red number plates) loaded with vegetables and heading in the opposite direction later in the day loaded with cement. The neat little two-storey concrete houses they build now dot the countryside surrounding Shanghai.

Intellectuals will have to wait some while for similar luxuries. Although accommodation is provided at very low rates, there seems little sign of any pay rises on the horizon. No concessions were given to intellectuals in the current five-year plan and the word is that they will have to wait for their reward until the next. □

On your bikes to Qinghua

REMEMBERING where you parked your bicycle can be something of a problem on Qinghua University's vast campus; there are ten thousand students and rows of identical-looking bicycles parked everywhere. Qinghua is the top "key" university for engineering (with different engineering departments covering every speciality) and took the Soviet technical university as its model. Its main building, seen here, is in the Soviet monumental style but elsewhere there are reminders of the university's origins. Traditional one-storey buildings with upswept roof-corners, vermilion pillars and classical rock gardens remain on one part of the campus, while a lecture hall with a domed roof and a Greek portico recalls the pre-revolutionary days when the university was a preparatory school for those going to study in the United States.

Also a surprise is that there are several factories on campus — the university even runs its own 2,000 kW power station. The factories are there for three reasons: to provide practical engineering training for students, to carry out developmental work, and to produce experimental equipment and manufacture goods for the market. Qinghua is successfully making a small computer, three types of micro-computer, machine tools, electronic components and precision tools. Research is often supported through contracts with in-

dustry, around 90 per cent of the university's research funds are gained in this way.

One of the university's top priorities is to improve the standard of teaching. Too many staff are poorly trained (blamed on the turmoil caused by the Cultural Revolution) and classes crowded, with lectures

Qinghua's parking problem outside the main university building.

attended by 100–200 students and seminars by 25–30 students. But noticeboards advertising lectures by visiting foreigners show there is considerable fresh input. □

Biotechnology

Planning for a model institute

CHINA's first biotechnology centre is just a scale model at present, but within two years everything from research laboratories (including four P3 labs) and animal rooms to a library and accommodation for visiting scientists should be complete. Some 57 million yuan have been set aside for construction and US\$5 million for buying modern instruments and reagents from abroad. Shanghai, where the institute is to be, has thus stolen a march on Beijing where plans for a biotechnology research institute are still at the discussion stage.

Shanghai has capitalized on its rich biological research community in going ahead with the centre: most of the 130 young research staff will come from the large Academy institutes of biochemistry, cell biology, physiology, medical research and the like. But capital to establish the institute comes from the central funds of the State Planning Commission.

Much of the centre's research will be in "traditional" fermentation according to its vice-director Sun Yu-kun, who came from the Institute of Biochemistry. A conservative approach is being taken because capital is scarce and the institute must make money soon; genetic engineering has a long way to go before it turns a profit and can thus occupy only a small part of the centre's activities. Nor is there significant experience in "downstream" processing in China; first attempts are likely to be the production of small peptide hormones in yeasts. Growth hormone, which can stimulate milk yields, is a likely candidate as its chemical synthesis has already been achieved in China.

A more conventional project being given thought is to use immobilized enzymes to turn the galactose in milk into glucose and thus increase its nutritional value. Others are the production of vitamin C through fermentation, a process developed in Beijing's Institute of Microbiology; and the production of penicillin acylase — used in the manufacture of semisynthetic penicillins — by a method developed at the Shanghai Institute of Materia Medica. Wherever possible it seems that techniques already mastered in China will be built upon. But these are early days and it is not yet clear exactly what line will be pursued.

Links with foreign companies are also likely and the centre is close to a contract with a European company to produce both monoclonal and polyclonal antibodies as diagnostic kits; no such commercial kits are yet produced in China. Foreign staff are also to be invited to the institute, along with guest researchers from other parts of China. But Professor Sun seems a little pessimistic about further

prospects for joint ventures; foreign companies often just want to sell their product or want too much money for their patents — even though they are interested enough in the China market.

In the longer term, there are hopes for a hepatitis B vaccine. With 10 per cent of the population carriers the need is obvious. But there is much work to be done before there is any hope of mass immunization for costs are still far too high.

Shanghai Institute of Biochemistry

The molecular biology revolution

SHANGHAI'S Institute of Biochemistry gained world-wide renown in 1965 when it brought off the complete chemical synthesis of insulin — a technical *tour de force* requiring a seven-year team effort. After insulin came the chemical syntheses of vasopressin, oxytocin, angiotensin and luteinizing hormone releasing hormone (LRH); and then in 1981 another technical triumph with the total synthesis of yeast alanine transfer RNA.

But now the institute's interests are turning more towards molecular biology. Indeed, this would have happened a lot earlier if it had not been for the Cultural Revolution. During that period the institute's fame enabled it to continue in operation; but only to perform the same kind of research. In the world outside molecular biology was blossoming but there was no chance of absorbing "foreign" learning.

Professor Zhang You-shang, who now heads the institute, and his colleagues are well aware that the real value of chemical synthesis is in structure-function studies; during the Cultural Revolution they had to treat synthesis as an object in its own right.

Rapid progress is now being made in

A nationwide plan is also being worked out for biotechnology by the State Science and Technology Commission and considerable stress is expected to fall on applications in agriculture and aquaculture. But Beijing's plans to set up several more biotechnology centres may fall flat for want of trained staff. Professor Sun, at least, believes it better to steadily expand one institute than waste resources on competing institutes. □

molecular biology. A sub-type of the hepatitis B virus (not the one found in the West) has been cloned and sequenced: the surface antigen was subsequently cloned in both *Escherichia coli* and yeast, but in neither case was expression sufficient for use in vaccine manufacture; vaccinia virus is looking more hopeful with clinical trials perhaps a year or two away. Numerous other projects are under way.

Problems of a different kind also much occupy the mind of the director who is in the midst of reconstructing the institute in line with the new reforms. What should emerge is a slimmed-down and perhaps stronger research institute with a brand-new molecular biology laboratory.

First, overstaffing has had to be tackled. During the Cultural Revolution, the institute grew larger and larger, with even unqualified senior middle school graduates sent to do research. There was no incentive to keep staff numbers down for funds were allocated simply according to the number of people employed.

Now that there is a financial squeeze on the way, the director is having to exercise his new powers of control over institute affairs. The institute has been divided into 39 research groups, with their leaders

appointed by the director. This did away with one level of hierarchy — the division — which previously isolated research groups. And the number of researchers in each group is now strictly limited. Researchers are appointed by group leaders on three-year contracts. But what is to happen to the excess researchers? If the new reform documents were interpreted literally, they could be sacked. But that is actually out of the question; a little persuasion has to be used to make them move elsewhere.

In essence, what is happening here and in other institutes is that those who are not

The legacy of the Cultural Revolution adds to Professor Zhang You-shang's staffing problems.

chosen to join in a research team receive neither space, equipment nor research funds although they will still be entitled to their salaries. Such "people to be appointed" as they are called, are given every help to find work elsewhere. But they will not be sacked.

Special difficulties come with some of those sent to the institute during the Cultural Revolution on the recommendation of peasants, workers and soldiers but who do not have formal qualifications. Some have proved successful but as Professor Zhang put it "some are not so suit-

THE meeting hall of the Chinese Academy of Medical Sciences is this magnificent old building just a stone's throw from the "forbidden city". The Academy's headquarters are just across the road, alongside the Capital Medical College which provided the base from which the Academy sprang. The hospital itself was founded back in 1921 and has been through a number of name changes according to the political climate — during the Cultural Revolution it had a brief spell as the "Anti-US Imperialism Medical University". The Academy now runs 19 research institutes, most of them in Beijing with two of the biggest, Clinical Medicine and Basic Medicine, on the central site. Nine thousand staff are employed with 400 at the professor and associate professor level. Strongest research areas are in cancer, particularly epidemiology and prevention, and cardiovascular diseases. But major weaknesses remain in basic medical research and biomedical engineering. □

able, but it is not so easy to transfer them now, they are not so young. If they transfer elsewhere they will have to start again at the beginning". Such workers are likely to stay on for a while doing various temporary jobs. What kind of personal strains these readjustments are causing — and they come on top of personal animosities that must have developed during the Cultural Revolution — Professor Zhang did not say, but one sensed that the burden of his task is not light.

There is good news for the institute too, though, in that it is to have a new Laboratory of Molecular Biology, funded by the government and the Chinese Academy of

Sciences, with the aim of providing facilities every bit as good as in Western countries. Indeed the laboratory's budget is to be as large as that of the parent institute itself. If anything, it is to be modelled on Cambridge University's laboratory of the same name, the permanent staff is to be small and visiting scientists, including those from abroad, are to be encouraged to come on contracts of 1–3 years. Three floors of the institute will be given up to the new laboratory; some of the changes needed to set it up are very simple: just installing air conditioning will make it possible to do research all year instead of having to stop in summer. □

Cancer epidemiology

Mapping the mortality risks

EVEN if China is a developing country, the major causes of death follow patterns very similar to those of the developed countries. So cancer is a major concern and, with hepatitis and birth control, is one of the three priority research areas earmarked by the Ministry of Health. Epidemiological research is given particular attention, partly because epidemiology leads the way towards prevention and partly because of the publication in 1979 of the *Atlas of Cancer Mortality in the People's Republic of China* (China Map Press), which revealed striking patterns of incidence of the different cancers across the country.

The atlas is an organizational *tour de force*. The survey on which it is based, carried out between 1973–75, covered 96.7 per cent of the population (approximately 800 million people). Ironically, the dispersal of many professional people to the countryside by the Cultural Revolution probably helped to make the compilation of the atlas possible and so may represent one positive outcome of this unhappy time.

Although the total cancer mortality (approximately 25 per cent of deaths) is similar to that in developed countries, the atlas shows that the overall frequency of particular cancers differs markedly from those common in the West. Stomach cancer is the most common form for both men and women in China. For men, oesophagus, liver and lung cancer follow in that order of frequency, while for women the order is cervix, oesophagus and liver. In Britain, for example, lung cancer is the most common among males followed by colorectal, stomach and prostate cancer. For women, breast cancer is followed by lung and colorectal cancer.

That environmental factors may be important is suggested by the marked variation of frequency in different parts of the country. Overall rates of death from cancer are highest in the south-east coastal provinces, in Shanxi in central China and in parts of the border regions with Mongolia. Nasopharyngeal cancer shows a strik-

ing focus in Guangdong and Guangxi provinces in the south where it is almost as common as stomach cancer, whereas in Xinjiang Uygur in the far northwest, it is rare. Cervical cancer shows very high rates in Shanxi and inner Mongolia. Liver cancer (see map) is highest in Guangxi and along the south-east coast — interestingly, across the water in Japan these cancers are also a major concern. Other notable features include cancer of the penis, admittedly rare, which occurs to a large extent in the areas of highest incidence of cervical cancer.

This huge database, together with accumulating knowledge of known or suspected cofactors — hepatitis B virus (HBV) in liver cancer, Epstein-Barr virus in nasopharyngeal cancer and smoking in lung cancer — have fuelled a search for other factors which may be important.

Sun Tsung-tang at the Cancer Institute, Chinese Academy of Medical Sciences, Beijing, is investigating the possible role of aflatoxins, the fungally-derived contamination of cereal foods. In Qidong county, Jiangsu, high levels of aflatoxin contamination of foodstuffs have been found. Liver cancer rates are also six times those in Beijing, but the frequency of HBV carriers is only 2.5 times as much. Sun plans a four-year study which aims to reduce dietary exposure by screening foodstuffs with monoclonal antibodies against aflatoxins and by chromatographic techniques he has developed.

The role of aflatoxins is also being investigated by the Shanghai Cancer Institute on Chongming island, in the Changjiang (Yangtze) delta, again a region with high rates of liver cancer. In a longitudinal study of 40,000 people, details of diet are being combined with an extensive investigation of aflatoxin contamination.

Shanghai has had a cancer registry since 1963. The city has very high rates of stomach, liver and oesophageal cancer in both sexes, but, most notably, very high rates of female lung cancer. About 50 per cent of Shanghai males smoke cigarettes and the attributable risk of smoking for

Age-adjusted male liver cancer mortality for 1973–75 in relation to the national rate.

lung cancer is 80.5 per cent. On the other hand, only six per cent of Shanghai women smoke, and the corresponding association is as low as 19.3 per cent. With poor ventilation and traditional practice, there is a possibility that cooking oil fumes may account for some of the high female incidence. Gao Yutang of the Shanghai Cancer Institute is carrying out laboratory and epidemiological studies; a causal study of 220,000 adults was begun in 1983 in collaboration with the US National Cancer Institute.

Dietary factors have also been implicated in stomach cancer. Zhang Rufu of the Beijing Institute for Cancer Research has analysed gastric juice from a total of more than 40,000 people in high-risk regions such as Gansu province in the north-west and Fujian in the south-east as well as in low risk regions elsewhere. High risk is associated with high nitrite levels and the fungus *Aspergillus versicolor* in the stomach. Atrophic gastritis is also more prevalent in these areas, possibly as a result of poor diet which, at the end of winter, can be dependent to a large degree in some areas on contaminated pickled vegetables.

It is too early to have a clear picture of the role of dietary and other environmental factors in the development of cancer, but given the heterogeneity of diet and surroundings in China and the heterogeneity of cancer incidence shown by the atlas, much may yet be revealed.

Nigel Williams

Polytechnic education

University as industrial partner

THE Beijing Polytechnic University (BPU) thinks of itself as China's version of the Massachusetts Institute of Technology (MIT), perhaps not now but sometime. It has a number of competitors, most obviously the Chinese Academy's own University of Science and Technology, transplanted south from Beijing to Hefei during the Cultural Revolution. In the long run, BPU's advantage may be its location in Beijing, which is where most people seem to want to live.

The university lives on a sparkling new campus in an industrial suburb of the capital. As in much of the rest of Beijing, buildings wreathed in scaffolding are a sign of things to come. The university's president, Professor Fan Gongxiu, is able to boast of a close relationship with the municipality of Beijing that should keep his institution in the forefront of the city's expansion for some time to come. And as at MIT, there are more tangible achievements to brag about — a state prize for the development of a laser printer (now being manufactured at Barbin, in the north-east) for example, and the second prize in the national Go competition. (Go is the

Dong Zhichang (right) and Zhang Zhi of BPU's Chemistry and Environment Engineering Department won a Beijing Science and Technology Achievements award for developing a crystal glaze.

board game sometimes counted as the Chinese equivalent of chess.)

By some other standards, the university is small. Student enrolment is 3,800 (of whom 300 are graduate students), but is expected to reach 4,500 by 1990. Usually, BPU sets out to recruit students who have already started work in industry, some 500 of them this year. As at other Chinese universities, the ratio of students to staff is luxurious (there are 1,250 members of the teaching staff, 750 of whom are professors or lecturers, and a roughly equal number engaged on other duties); the explanation is that a student's enrolment entails total responsibility; students must not be merely taught but housed, supervised and even instructed in what is called "political science".

Stimulated by an experiment in educational reform launched in 1983 by the municipality of Beijing, the university has paid special attention to "moral education", which takes the practical form of

engaging students on social work among old people and the like.

The most striking sign of what the university does for industry is the source of its funds; this year, 8 million yuan will come from the central government but 6 million yuan from industry. On top of that, the university has this year brought in 4 million yuan for research, chiefly as research contracts with industrial enterprises.

The demand for the university's services as an industrial partner has meant that 20 substantial projects have been turned away this year. Selfconsciously, the university reckons to be able to choose the projects with the "best economic value", but a collaborative research project will not be undertaken unless there is a suitably qualified member of the faculty who is, moreover, willing to take on the responsibility.

So what impression of the quality of industrial research in China has this well-placed university formed? Professor Fan acknowledges that many (but not all) industrial enterprises are much in need of skilled technical people, but he does not agree that industry needs always to be capable of carrying out its own research and development. That may be the pattern in the West, but in China it may make sense, and economize in scarce resources, that institutions like BPU should take on central research and development for a group of industries.

Often, it seems, the intimacy of the relationship threatens to turn the university into an industry in its own right. In 1981, Fan says, the industrial design department at the university embarked on a study of single-board microprocessors, from which sprang no fewer than a score of novel designs. So now the university has a factory with 100 workers which, last year, earned 20 million yuan from the sale of its products. Among other things, Fan says, the factory is a model for other factories elsewhere in China.

The curriculum at BPU is rigorous, perhaps even more so than at MIT. The standard course lasts for five years, beginning with basic science instruction. There is a language laboratory to ensure that everybody has a chance to learn some language other than Chinese, and facilities for art instruction and practice. Project work plays an important part in the curriculum in the later years of the course, and BPU reckons to do exceptionally well in the national competitions regularly organized in China for those with engineering innovations to show off.

For a university as new as this (BPU came into being only in 1960, directly under the wing of the municipality, and most of its work was suspended during the Cultural Revolution), international relationships are prominent and strong, espe-

Fighting restrictions

LIANG Zhiquan (left) and Shen Yufei in the Department of Molecular Biology and Biochemistry at the Institute of Basic Medical Sciences (Chinese Academy of Medical Sciences), Beijing. Founded in 1919 as part of the Beijing Union Medical College, it now has a scientific staff of around 370 and the largest department is that of molecular biology.

The emphasis is basic work on well-defined Chinese medical problems. As in Shanghai (see page 217), a hepatitis B virus subtype has been cloned and sequenced — an essential step towards the production of a recombinant vaccine. The use of gene probes to study and detect prenatally α - and β -thalassaemias, which are quite common in Guaxi, Guangdong and Sichuan, is being developed by Wu Guanyu in collaboration with other institutes in the affected regions. Successful prenatal diagnosis of α -thalassaemia has been carried out.

A new and important role for the institute is the development of restriction enzyme production and Qiang Boqin is keen to hasten the time when China can be self-sufficient in these reagents.

Progress at the institute has somewhat overwhelmed the old buildings, but hopes are high that brighter more spacious accommodation will be available in a new building within four years.

Nigel Williams

cially with institutions such as the State University of New York at Buffalo, Northeastern University and the like. One objective is to let potential members of the Beijing faculty complete their studies in a stimulating environment, another to add to the university's competence in industrial research.

Among the young people of Beijing, BPU is clearly a favoured institution. In the annual competition for university entrance, some 7,500 students a year, or roughly ten times as many as the annual entry, put BPU first on their list of desirable universities. So why not grow faster? Fan's reply contains an element of paradox: even an industrially oriented university should not grow too quickly for the health and wellbeing of China's industry. But, secretly, the objective may be to avoid jeopardizing quality in the chase for numbers. □

Plant taxonomy

South China's germ-plasm tank

TRANSPLANT the Royal Botanic Gardens, Kew, from the suburbs of London to a subtropical climate and you would have the South China Institute of Botany, twenty tortuous kilometres from downtown Guangzhou, the provincial capital of Guangdong. But the institute has long since outgrown its role as the taxonomic centre of luxuriant South China, with interests that range from plant ecology to agricultural botany.

The origins of the institute parallel in interesting ways the emergence of modern China from its feudal past. Guangdong was the base from which, in the 1920s, the revolt against the surviving feudal barons was organized by Dr Sun Yat Sen (after whom the university of Guangzhou is named). The province then had the sense of being at the centre of reform in China. For a time, in the 1920s, an island in the Pearl River was the site of the military academy whose students at various times counted among their number not only Mao Tse Tung and Chiang Kai-shek (later the Kuomintang leader) but also Zhou Enlai, the Chinese Prime Minister in the period immediately after the Cultural Revolution.

By 1928, the plant taxonomist Chung, then based at the Sun Yat Sen University, embarked on an ambitious taxonomic study of South China. Over the succeeding twenty years, undisturbed by revolution, invasion (by the Japanese) and civil war, Chung and his team, which never exceeded 26 people, scoured the region for plant specimens, which now make up the core of the institute's herbarium, a vast collection of 600,000 dried specimens. Soon, the institute hopes, the herbarium catalogue will be computerized. And there are plans to transfer the whole of the herbarium to an air-conditioned building.

The present director, Dr Kuo Chun-Yen, has his intellectual roots in the Middle West of the United States; a graduate of the University of Shanghai, he took himself to the University of Chicago for graduate studies in 1947 and was then stranded at the University of Michigan (at East Lansing) because the United States and the new Chinese People's Republic did not establish diplomatic relations with each other until 1955. The result is that Kao bubbles with enthusiasm for the plant-breeding unit that covered the Middle West with hybrid corn in the 1960s. In September this year, he was packing his bags for yet another visit to East Lansing, an extended stay supported by the US National Academy of Sciences.

Kao's interests in agricultural botany reflect the present pattern of the institute's work. The establishment was moved from the university to its present site in 1954, and four years later spawned

the adjacent 30 hectare botanic garden. The subtropical climate has ensured that, in a mere thirty years, traces of the previous army barracks have been obliterated by lush green vegetation. In 1955, the institute also acquired the 1,200 hectare site in the mountains southwest of Guangzhou which has become an arboretum of such distinction that it is likely to be the centre of one of UNESCO's Man and Biosphere projects.

Nationally, the South China Institute is one of three laboratories whose interests between them span the whole taxonomy of Chinese plants (the others are at Shanghai and Beijing). Jointly, the three institutes have embarked on the compilation of a comprehensive Chinese flora, a gigantic undertaking whose timescale remains undefined. But in practice, the institute's interests inevitably centre on the agricultural needs of South China. The techniques of meristem culture have become the spearhead of plant breeding, here as elsewhere in China. Kao is especially pleased with a project, now in the development stage, to propagate a species of begonia growing naturally on rocky surfaces which has been collected almost to extinction on account of its medicinal properties (but which, in any case, makes a pleasing tea-like beverage). Kao emphasizes that the topography of much of China is unsuitable for the growth of paddy rice, for which

reason there is a great need for the development of other kinds of crops. Kao figuratively snaps his fingers with frustration that the Chinese gooseberry has been transmogrified into New Zealand's kiwi fruit. The institute is engaged in the general concern to develop crops that may be grown successfully on the island of Hainan, the strategically important island off the south coast of Guangdong that faces North Vietnam, as well as in what seems to be the national concern that lychee fruits should be prevented from deteriorating during their distribution.

By most yardsticks, the South China Institute is a huge laboratory, with a staff of 560, of whom 260 are scientists with degrees. It is as well equipped as anybody could ask. As at most other laboratories in China, there is a curious contrast between the internal finish of laboratory buildings, which seem unusually to be shabby sources of powdered cement dust, and the spick and span appearance of the instruments, mostly newly imported from overseas.

Like the other major institutes of the Chinese Academy of Sciences, the South China institute is an important centre for the recruitment and training of professional scientists. The competition for a place at the institute is keen, not least because it seems to be generously provided with funds to support travel overseas. For the past six years, the institute has been regularly sending people to work overseas not merely so as to read for PhD degrees at universities in the West but also

Fudan powers nuclear industry

STANDING around president Xie Xide in the photograph below are the senior science staff of Fudan University, one of China's top comprehensive universities. In contrast to nearby Japan, women professors in science faculties are not uncommon.

Fudan University was set up in Shanghai in 1952 in the days when a major first task of staff was to translate Soviet textbooks. Nowadays, most staff have been to study in the United States or Europe and the university is adapting to the new open policies. A new School of Technological Sciences

was set up last year, not to train engineers, but to produce top graduates with the scientific grounding necessary for research and development. Among research in progress is work on oil prospecting software for a homebuilt high-speed computer, zeolite catalysis, control of pests by viruses, and VLSI (very large scale integrated circuit) photoresists. There is also one of the nation's few departments of nuclear science, some of whose graduates will go to the new nuclear power plants now being constructed.

The teaching system is also becoming more liberal with students allowed to choose courses to go with their majors and the introduction of a US-style credit system. There is talk — as in Qinghua University — of an exam at the end of the first year to weed out students who are not making the grade, although it is bound to face opposition. Like universities elsewhere the staff is divided into those who do research, and those who mainly teach with perhaps a third of their time free to research. Rotation between groups takes place, but irregularly. Research facilities have much improved in the past few years with a massive infusion of new imported equipment into the science building.

Left to right: Hua Zhong-yi, vice-president; Zheng Qi-ke, nuclear science; Wang Li-hui, materials science; Xie Xide, president; Wu Li-de, computer science; Su De-ming, biology department; Zhou Dun-ren, foreign affairs; and Gao Zi, chemistry department and recently at Imperial College, London.

to work on collaborative projects. As part of a collaboration with the University of Utah on photosynthesis under the auspices of the Carnegie Institute of Washington, for example, Kao has two of his people at Salt Lake City on a five-year stint.

Reform has also begun to make its mark. The research programme at the institute is being formally evaluated by a committee including people from outside the institute, and a process has been set up for assessing the performance of individual researchers so that, over the years, people can be persuaded that their personal interests coincide with the national interest that the scientific labour force should be more mobile.

As elsewhere, the Cultural Revolution is philosophically regarded as a phenomenon belonging to the past. Kao and many of his staff were sent off to the countryside at the beginning of the upheaval, but he says that after a little while, they were able to move some of their equipment into exile as well, and get on with their work. During the period, they were able to produce three volumes of advice for barefoot doctors on the medicinal use of Chinese plants, as well as giving some of the peasants with whom they worked first-hand instruction on the use of new techniques and novel cultivars. And even now, on a strictly voluntary basis, the laboratory thinks it worthwhile that some of its scientists should work closely with peasants in the countryside, providing some of the services of what would elsewhere be known as agricultural extension services.

Guangzhou's botanic garden is the creation of an Edinburgh-trained agronomist, Professor Chen Fung Huai, now 85 and living in retirement in the grounds of the South China Institute. Chen is now a frail shadow of the man who, in the period after 1949, seems to have made it his personal mission to scatter botanic gardens about China.

Botanic gardens, he says, are not parks or playgrounds, but "open-air laboratories". Each new site is a different challenge. People have to worry not simply about the climate but the pH of the soil, and must be able to guess how the microclimate of each part of a new garden will change as it matures. During his career, Chen has founded botanic gardens in places such as Beijing and Nankin.

Chen is now the South China Institute's most distinguished resident. Kao, the director, says that he has to take care to preserve Chen's energy, protecting him from visitors whenever possible. It is one mark of the way in which ties between China and the rest of the world have survived the upheavals of the past half-century that it should be possible to have a polite conversation about the temper of a Scottish university in the 1930s in such a faraway place as this suburb of Guangzhou. □

Guangdong

The centre is a long way away

SOUTH China is as different from North China as is, say, Louisiana from Massachusetts. The topography, to be sure, may look much the same, but heat and humidity give both southern regions a distinctive sense of being different. But there is another influence in South China — Hong Kong and, to a lesser extent, Macao. The free port ("special economic zone") surrounding what are called, in Hong Kong, the New Territories is the most successful of the four now operating, and has acted like a magnet in shaping the direction of economic activity in the province of Guangdong. One curious sign of the proximity of Hong Kong (about 100 km away) is that it has been for the past year permissible for people in the province to watch Hong Kong television programmes (for which purpose an imported receiver is required). There can hardly be any greater contrast than that between the staid Chinese channels, which broadcast Party meetings, accounts of industrial improvement and scenes from well-ordered family life, and the steady output of violence by video that distinguishes the Hong Kong stations.

Guangzhou, the provincial capital, is also the seat of a branch of the Chinese Academy of Sciences, a distinction that is somewhere in between an administrative decentralizing step and a means of recognizing the importance of a provincial centre. But the Guangzhou branch differs from that in, say, Shanghai in that its relationship with the provincial government is close. Formally, there is a Guangdong Academy of Sciences which is directly responsible for the seven provincially supported research institutes, and which manages the local branch of the national academy as well.

With travel restrictions inside China eased, the Great Wall is always full of tourists from all over the country.

Thus the local branch is a kind of Cantonese contract manager of the six institutes of the Chinese Academy of Sciences in the locality (oceanography, geology, chemistry, electronic technology and energy conversion as well as the South China Institute of Botany — see opposite). The clutch of institutes financed by the provincial government, in fields such as geography and microbiology, serve largely provincial needs; officials are proud that, in the past few years, the attention the microbiologists have paid to the improvement of mushroom strains has, for example, made it possible to increase the income of peasant mushroom growers by 10 million yuan a year. Another proof of Guangdong's capacity to look after itself is that the Academy seems to have been able to open a new research institute, that for electronic technology, at the height of the Cultural Revolution.

For all its operations, the Guangdong Academy gets 25 million yuan a year from the Beijing Academy and 7 million yuan from the provincial government. Officials of the local academy are enthusiastic supporters of the government's policy of modernization. They see it as one of their principal tasks to persuade more scientists into industrial employment, to which end they are doing everything they can to have their own institutes work more closely with industrial partners.

The Guangdong management is plainly not informed of every detail of what its institutes are up to in these fields, however — the central office had not learned in late September that its institute of electronic technology had sold a software package to a Hong Kong company for HK\$100,000. But that is entirely within the rules. Only if the earnings of individual institutes became a large proportion of their budgets would it be necessary to consider whether the income should be used to help finance other institutes.

Coping with growth may be Guangdong's only source of serious worry. For the time being, the officials say, there is enough money to keep the institutes hard at work. The supply of people is sufficient, but there is some concern about the quality of those leaving the universities. Equipment is no great problem now that the institutes with research reputations can get their hands on foreign exchange.

So should not something be done to improve the universities, and to increase their intake of students? Here again, Guangzhou echoes Beijing. For the time being, there can be no substantial increase of the university population. The immediate hope is in continuing education, either at the workplace or by private study, with help provided by educational television programmes. □

Shanghai biology

Largest city looks to itself

SHANGHAI, China's largest city (on the strength of its ports and industry), has every reason to regard Beijing, China's capital, as an administrative centre somewhere to the north. The relationship between the two cities resembles, for example, that between New York and Washington DC, or, in the nineteenth century, between Manchester (England) and metropolitan London. This is the spirit in which Shanghai takes pride in being one step ahead of the capital. Institutes of the Chinese Academy of Sciences at Shanghai have thus been first in the field with the synthesis of insulin, and have designed China's indigenous nuclear reactor.

Another sign of the way the wind is blowing is that the local branch of the Chinese Academy of Sciences is now busily welding together on a single campus a clutch of biological institutes that, between them, will have more than 3,000 qualified people on their books. The intellectual architect of this scheme is Professor Cao Tianqin, now the president of the Academy's Shanghai branch and director of its division of biological sciences.

Apart from the biochemistry institute (of which Cao was the director until a few years ago), there are institutes of physiology (housed in a Victorian gothic mansion), organic chemistry (oriented towards natural products of medicinal value), materia medica (more so), cell biology, brain research, plant physiology and entomology. The laboratories are united into a kind of common purpose, not the least by an ambition to be doing today what Beijing may do tomorrow.

The Shanghai institutes are especially proud of their overseas connections. Cao took his PhD at Cambridge. Professor Mei Zhen-Tong, the woman who is director of the Institute of Physiology, is similarly trained overseas. Professor Chang, who founded the brain research institute by fission from physiology in 1981, had returned from a distinguished career at the Rockefeller Institute, New York, and at John Hopkins. The Australian connection is also conspicuous at Shanghai, especially in plant physiology and entomology.

This complex of laboratories is splendidly equipped. During the past few years, there seems to have been very little restraint on the supply of hard currency for the purchase of equipment, so much so that there are occasional signs that some of what has been bought in from overseas has not yet been used for its intended purpose. One mark of the state of the equipment at the Shanghai institutes is that the important suppliers from the United States and Europe have thought it worthwhile setting up agencies in the city.

Although most people in these biological laboratories recognize that the future lies with molecular biology and its applica-

tions, for the time being there are two serious impediments. First, in spite of many efforts during the past few years, plans to provide a central agency for the supply of essential reagents such as restriction enzymes have not succeeded; the purity and activity of the indigenous products are variable, so that too many researchers and their helpers must spend precious time making their own. Much the same applies to the supply of radioactive chemicals. The specific activity of reagents labelled with active carbon is never great enough to satisfy the molecular biologists.

Meanwhile, there is no shortage of interesting work on hand. The organic chemistry institute, with a total of 1,200 members of staff (500 or so employed on pilot-plant work) spread their interests from the role of nickel and molybdenum in catalysis to the search for medicines. One such success is the characterization and purification of an abortifacient in a traditional medicine which consists of a polypeptide with 230 amino acids. In the pure form, microgram quantities of the material appear to be effective. The laboratory itself is manufacturing the material for distribution in China, and estimates that more than one million women have so far

Acupuncture boom punctured

ACUPUNCTURE is still widely used in China for the treatment of various ailments, rheumatism, for example. But there now seems to be a retreat from the assertion, common during the Cultural Revolution and believed by many Western physicians at the time, that acupuncture can be an effective analgesic in surgical operations.

Dr Jiang Zhen-yu (C.Y. Chiang), from the Shanghai Institute of Physiology, is judiciously cautious on the present use of acupuncture. He says that the ministry of health has put out a decree restricting the analgesic use of acupuncture to operations on the thyroid, the diaphragm and similar procedures. The general use of anaesthetic acupuncture has otherwise fallen into disuse. And there is no means of telling how widely practised are the uses allowed by the government decree.

Jiang insists that the new scepticism does not extend to the therapeutic use of acupuncture. In saying that, he reflects one of the most striking features of Chinese health care to visitors from abroad: the apparently easy coexistence of scientific and traditional medicine. The explanation, to scientist apologists, is that traditional medicine will be found to be just as objective when biochemists have identified the active principles of traditional remedies, dried bears' gall-bladder (a treatment for kidney stones), for example. □

made use of it. The obvious next step is to tell which parts of the molecule are essential for the biological activity in the hope that synthetic production will be possible. Similarly, there is a continuing hunt for antimalarials; the active principle of the *Qinghan* species, identified at the laboratory in 1979, has now been synthesized.

Between them, the Shanghai biology and biochemistry laboratories span a vast range of interests, from neurophysiology and the search for new drugs to classical environmental physiology.

The laboratories also have a crucial educational role. The organic chemistry institute alone has 150 graduate students, and is now selecting 6 or 7 MSc graduates a year for its PhD programme. With the help of imported computer equipment, the laboratory is also setting itself up as a national centre for chemical data.

Most people in this Shanghai complex think they will do well out of the reform. The good basic research people, they say, will succeed in the competition for research grants from the National Science Foundation, to come into being next year, while those whose work has practical applications (the cell biology institute, for example, is strong on the endocrinology of fish reproduction) will also thrive.

The cell biology institute hopes, under the reform, to become an "open laboratory", a distinction that would allow it to take in researchers temporarily from university departments, to be more free than at present to spend funds on overseas travel and on inviting visitors from overseas. (Already it has a suite of laboratories, paid for by the West German Humboldt and Thuyssen foundations, which houses two West German doctoral scientists in spectacular luxury by Chinese standards.) But greater freedom in the selection of graduate students is ultimately the prize.

Under the new system, will it be possible to safeguard the interests of basic research? Most of the laboratory managers are conscious of the need, even when they add that China's industry is too short of skilled help. The most obvious danger is that even when people succeed in the competition for research grants from the National Science Foundation, their salaries will remain what they are at present, while there is at least a chance that colleagues who work on industrial contracts will find that their personal rewards are substantially greater than their salaries. Given the resentment about the poor rewards of research now building up in the laboratories, laboratory managers will be tempted to share outside income on some egalitarian basis. But even so, laboratories concerned primarily with basic research will be at a disadvantage. Nevertheless, the president of the Academy of Sciences, Professor Lu Jiaxi, says in Beijing that "they'll have to wait another five years" (until the next five-year plan) to share in China's growing prosperity. □

High-energy physics

Towards home-grown mesons

WHY should a country such as China be building a particle accelerator when countries such as Britain wonder whether they can continue to belong to international organizations such as CERN, the European high-energy physics laboratory at Geneva?

The answers are various. The technology of accelerating charged particles is valuable in itself. Worthwhile accomplishments in such a field are a necessary price to pay for collaboration with others. And in any case, as the economy of China grows to match those of the large industrial nations, it will be natural that China should be in high-energy physics.

But the clinching argument is probably similar to that which sustained high-energy physics in Britain and France in the 1960s; there is a group of Chinese physicists with ability and political influence who consider that China without an accelerator would be a contradiction in terms. Even though the ambitions of the period immediately after the Cultural Revolution have been scaled down, the government is generously backing construction of a 2 GeV electron-positron collider.

The result is the large elliptical hole in the ground now taking shape at the Institute of High-Energy Physics at Beijing. By 1988, this will have been equipped with the appropriate vacuum chamber and magnets, within which there will circulate two oppositely directed beams of electrons and positrons, each beam with an energy of 2.2 GeV.

In these terms, BEPC (for Beijing Electron-Positron Collider) will be most closely comparable to the electron-positron collider called SPEAR II, which operates at Stanford but the design group hopes to attain a luminosity (collisions per square centimetre per second in the colliding region) greater by at least an order of magnitude (specifically $1.7 \times 10^{30} \text{ cm}^{-2} \text{ s}^{-1}$).

This, of course, is both a far cry from the energy of machines such as LEP (being built at CERN), which should give electron and positron beams of 86 GeV with the possibility of an extension to 135 GeV per beam. It is also a far cry from the plans announced at the great national meeting on science and technology in November 1978, when the ambition was to build a machine for accelerating protons to 50 GeV (a more powerful version of CERN's super-synchrotron, say).

That was the goal as recently as four years ago, but detailed design work showed, according to vice-director Zhang Houying, that the cost had been underestimated by 1,000 million yuan or so. The machine now being built is a utility electron collider; the energy of each beam can be tuned between 2.2 and 2.8 GeV, but the option of extending the beam energy to 4.7 GeV has been dropped. To begin

with there will be only one point on the storage ring at which electron-positron collisions will be induced (with provision for a second colliding zone to be added later) and the storage ring will be equipped with an oscillating magnetic field to generate synchrotron radiation with usable flux in the keV range.

One relic of the heart-searching of the past few years is a 35 MeV linear accelerator for protons, built almost entirely from Chinese components, which is being ingeniously converted into a means of generating fast neutrons (for the treatment of cancer patients) and short-lived isotopes.

BEPC itself is the result of a government decision at the highest level (the

Beijing's storage ring takes shape.

State Council). The cost of the construction phase (240 million yuan) is being borne directly by the government even though the institute is an integral part of the Chinese Academy of Sciences' network. ("We couldn't afford it", said one Academy official.) According to vice-director Zhang, the eventual running cost of the new machine will be some 20 million yuan a year; it is still not clear which part of the government will meet the cost, but the Academy seems determined that it should be the government direct.

Since the ground-breaking ceremony in October 1984, work has pushed ahead quickly. The 201-metre tunnel for the injecting linear accelerator (which will produce alternately electrons and positrons at 1.1 GeV) is almost complete, 8 metres below ground level. Concrete is being poured for the containment walls of the tunnel to house the storage ring. Construction should be complete by the end of 1986, with operation 18 months later.

Intrinsic interest apart, BEPC is a marvellous illustration of the problems of building a big high-technology machine in China. Part of the objective has been to

demonstrate, for self-confidence if no other purpose, that the design can indeed be carried through; so the control system (which detects the positions of the electron and positron beams, adjusting the magnetic fields to keep the beams on course) has been elaborately designed around a network of novel Intel integrated circuits.

But as yet, the design is unfinished; last month, no fewer than 15 people from Beijing were working at the Stanford Linear Accelerator Center on the details of a design that will, with luck, incorporate the latest in accelerator technology.

The physical components of the accelerator are more teasing problems. According to Zhang, the sections of the aluminium vacuum chamber are being made in the United States because they are cheaper that way (\$50,000 against 700,000 yuan). The same applies to electronic components, which are 1,000 times as expensive in China as in the United States.

On the other hand, the klystrons that will generate the microwave power to accelerate electrons in the linear injector section are to be made in China because their export from the United States is forbidden; the high-energy physics institute has had to rely instead on the Ministry of Electronics to commission the manufacture of the 16 klystrons required for the linear accelerator (peak power output, 15–20 MW at 2.856 GHz), no doubt to the benefit of China's defence industries.

The US government has nevertheless relaxed the strategic embargo to allow the purchase of a VAX 11/830 computer after 18 months of negotiations, but in return for a promise that the machine will be used only for the collection and processing of data from the drift chamber detector being built for the sole experimental section of the storage ring.

What will the machine accomplish? Some physics, without doubt; even by 1988, the products of electron-positron collisions with total energy between 4 and 5 GeV will not fully have been worked out. There will be plenty of charmed mesons and the institute intends to concentrate on careful measurements of the properties of these particles and the details of the decay of the heavier analogue of the electron and muon (the tauon).

The more enduring objective is to show that China can build an accelerator, and in the process win access for Chinese physicists to more powerful machines being built elsewhere. Already there are members of the institute working at Brookhaven and the National Accelerator Laboratory (Fermilab) in the United States, as well as at Stanford and CERN. The institute also hopes that its new machine will become a focus for collaboration with other developing countries.

For reasons such as these, the institute seems not to be under serious pressure from the government to be more directly

involved with industrial development, some of which is in any case stimulated by the need to develop novel components for the accelerator. With more than 2,000 people (1,200 of them scientists and engineers), the institute hopes to have more than 100 graduate students in the year ahead and a quota of 10 postdoctoral fellowships a year, chiefly as a means of holding onto those returning from abroad.

Curiously, the institute seems to have been spared the worst excesses of the Cultural Revolution, although people like vice-director Zhang (an electrical engineer) spent much of the time as a member of a cadre work-school laying electric-

ity power lines. Its partial immunity seems to have stemmed from a Maoist dictum that it is important to "keep on dividing the constituents of matter" as well as from its antecedents; the institute is an offshoot of the Institute of Modern Physics established in Beijing in 1950, from which has also sprung the Institute of Atomic Energy (in the southwestern suburbs of Beijing) and, less directly, the Shanghai Institute of Nuclear Energy (responsible for the design of the 300 MW indigenous reactor) and the Lanzhou Institute of Modern Physics with a programme of low-energy nuclear physics. The Moscow Institute of Physical Problems is the closest analogue.

Space programme

Next, the non-stick heat pipe?

CHINA in space is not the joke suggested by its first satellite, launched on 24 April 1970, and still affectionately remembered for its broadcasts (audio, not video) of a folk song. Indeed, there are no doubt many who would consider that the rapid development of China's rocketry is almost the opposite of a joke.

On the civilian side, China has since 1970 launched a total of 16 satellites. Last year (8 April) the Ministry of Astronautics succeeded in putting a small satellite into a geosynchronous orbit, preparing the way for the series of telecommunications and broadcasting satellites scheduled for next year and thereafter.

Indeed, the ministry is now talking up the possibility of selling launching facilities, just as do the managers of the Ariane and US shuttle programmes. Zhang Jiqing, an engineer with the ministry and director-general of what is called the Foreign Affairs Bureau, says that there have been conversations about satellite launchings with the Netherlands, Sweden and even the British government (represented by the Rutherford Appleton Laboratory of the Science and Engineering Research Council, a grant-making agency). But nothing has yet been fixed.

The ministry says its interests are entirely civil, but it goes without saying that the civil space programme is an outgrowth of the military programme on whose behalf patches of the Pacific Ocean are from time to time declared out of bounds to shipping so that a military rocket may plump down without doing damage.

Indeed, Zhang's simple answer to the simple question of what a developing country such as China is doing in space is that the country has a need (for telecommunications and broadcasting satellites especially) and also the means. The liquid-fuelled rockets (using unsymmetrical dimethyl hydrazine as fuel, burned with liquid oxygen) have been labelled sequentially as "Longmarch" I, II and III, with IV and V under development. They have their roots in a series of developments thirty years ago, when the military rocket

programme was begun.

There is a host of research institutes catering for the needs of the military and civil space programmes, many of them the property of the Ministry of Astronautics, others operated by the Chinese Academy of Space Technology, which is itself influenced (and partly financed by) the National Commission for Science and Technology for National Defence, constitutionally similar to the civilian academy on which the Chinese Academy is dependent.

There are special research institutes in fields such as microelectronics, but the design and fabrication of launch vehicles is the responsibility of an industrial organization, the Wangyuan Industrial Corporation.

There is no reason to doubt what people such as Zhang say about the civilian character of his ministry, which seems to have been hewn out of the defence establishment, and given a separate identity, so as to allow military development to continue in isolation — and secrecy. In this diligent separation of the two faces of research,

China has followed the Soviet Union in its organization.

But China's special claim on attention, according to Zhang Jiqing, is the development of techniques for recovering satellites from orbit (by means of a retrorocket and a parachute) and the use of a single rocket for launching several satellites. There is nothing remarkable about the sequence in which the rockets at the ministry's disposal have been developed. The first was a three-stage affair, with two liquid-fuel stages and a solid-fuel booster on the top.

The workhorse of China's space programme until recently, Longmarch II, had two liquid stages, and has been used on nine occasions, with only one failure right at the beginning. Longmarch III, according to Zhang, has three stages, of which the uppermost is fuelled by hydrogen and oxygen; he says that it is comparable with the first version of Ariane 1 in that it should be capable of putting 1 tonne of mass into a low orbit in preparation for putting part of the mass into geosynchronous orbit. Improvements now being undertaken, Zhang says, will increase the masses by a half, so as to put 1 tonne, typically the weight of a communications satellite, where it can be useful.

The scientific programme has concentrated so far mainly on the measurement of energetic particles and cosmic rays. Chinese researchers with plans for satellites must first convince their institutes of the good sense of their proposals, whereupon the institute and its parent agency will seek to negotiate launching space.

Plainly, this process is as tortuous in China as elsewhere. Thus one of the boasts of the Guangzhou Institute of Electronics is that it has already finished work on the design and construction of the data acquisition kit intended for an astronomy satellite "soon" to be launched, and that it has already sent the equipment to Beijing.

A sextant, quadrant and celestial globe built by the Jesuits for the Qing emperors are on display at the Ancient Beijing Observatory, a massive gate that was once part of the city walls. Kublai Khan built the first observatory here in 1296. More recently, some extra "stars" were added to the celestial globe when it was pierced by Japanese bullets during the occupation of China.

Zhang, speaking for the Ministry of Astronautics, says that he knows of no plans to launch such a satellite.

Inevitably, the ministry employs technical people on a huge scale. Zhang estimates that its technical staff numbers 20,000, perhaps a quarter of them with university degrees. The ministry seems to have first claim on the output of graduates from a number of university departments as well as its own specialized college.

The ministry seems well aware that its chances of winning business in the market for launching satellites will turn crucially on its domestic success, whence the importance attached to the launching of a full-scale but still experimental telecommunications satellite early next year. The first television broadcasting satellite is now being built, but will not be launched until 1987 or 1988. There are also plans for meteorological and Earth resources satellites.

So is all this effort worthwhile, at least

at this early stage in the industrial development of China? One important spin-off, according to Zhang, has been that China has been required to set up factories for the manufacture of the special materials needed in the space programme, and in the process has acquired novel technology. The fly in this ointment is that many of the factories built for this purpose have been isolated from other general-purpose enterprises, but Zhang thinks that may change now that the government is doing everything it can to encourage mobility within the economic system.

Asked for a specific example of an innovation within the space programme that had found more general application, Zhang (after some thought) offered the case of the heat pipe (a way of transferring large amounts of heat by means of liquid metals), which is slightly reminiscent of the US NASA boast in the 1960s that the space programme had given the world the non-stick frying-pan. □

The aperture synthesis metre-wave radio telescope at Miyun, outside Beijing.

will soon have a station. A 25-m antenna facility for the 1–20 cm waveband which can link up to the world network is almost complete at Shanghai. As the only station in this part of the world it will be highly valued.

Solar studies, another relatively inexpensive area, and of practical use in predicting magnetic storms which disrupt telecommunications, are also well developed, at least in the more classical areas. New equipment coming into service includes a very fast recording solar heliometer telescope at Beijing University. A new telescope for observation of the fine-structure of the Sun is now complete at Yunnan Observatory and another will come into operation at Nanjing Observatory next year. Several major expeditions to observe eclipses have also been mounted and made good use of the unique observing conditions available in the Himalaya and Karakorum mountain ranges.

A unique site — in the Chaidamu Basin in the Gobi desert — has also been found for the new millimetre-wave telescope. It is quite high (3,000 m), flat (which makes it easy to do interferometry and to build roads) and very cold. That means there is very little water vapour in the atmosphere which makes for much higher resolution than comparable instruments at sea level. A 13.6-mm imported telescope will be run by the Purple Mountain Observatory and should be in operation next year. Here China can make major contributions for many molecular lines remain unexplored.

An attempt to fill an empty niche is also being made with the Miyun radio telescope. A set of antennas used for solar interferometry has been expanded into an aperture-synthesis array operating in the metre waveband (232 megahertz). Expensive and sophisticated centimetre-wave telescopes are already in place in the United States and United Kingdom so the telescope was designed for wavelengths they will not reach. Nor will the very large arrays now being built come to these wavelengths so Miyun should provide unique data for years to come. At present a two-year survey of the whole northern sky is under way. Any new variable stars, stars of unusual spectral type and the like that turn up among the 100,000 or so sources expected to be present will be studied in more detail later. □

Astronomy

Things could be looking up

NEW astronomical facilities are appearing one after another in China: completed this or last year are a metre-wave and two solar telescopes; and nearly complete are a very long baseline interferometry (VLBI) station, a millimetre-wave telescope, a 1.2-m infrared telescope, and a 2-m optical telescope. But it would be an oversimplification to say that Chinese astronomy is booming.

As Professor Wang Shouguan, director of Beijing Observatory explained, the apparent burst of activity is more a matter of the Cultural Revolution having synchronized many projects. It was back in 1957 that a large optical telescope was first planned, for example. But then the Cultural Revolution came along and different parts of the telescope were slowly built at different places. Engineers are now just completing the daunting task of remodelling the parts to fit them together (which is "worse than doing it from new") and then the telescope — a 2.16-m reflector — will be installed near Beijing next year.

Major observatories have been built at Beijing, Purple Mountain (Nanjing), Shanghai, Yunnan, and Shaanxi (a relatively new time-service observatory) with the largest optical facility a 1-m telescope at Yunnan. But a new 1.2-m infrared telescope will be in operation at Beijing Observatory by the end of the year. Undergraduate courses in astronomy are given at Nanjing, Beijing Normal and Beijing universities and the Academy's University of Science and Technology at Hefei has an astrophysics centre for graduates.

Overall, China's astronomical facilities are quite modest. But that is not necessarily a bad thing. Professor Wang sees the immediate aim as training a corps of young

scientists, and for that small to medium-sized facilities are excellent because you have to "think hard to get the most out of them". When Chinese astronomers are more sophisticated they can try some really big projects. And even if more money were available Professor Wang's own view is that it should go on laboratories, computers and young people rather than big telescopes. That being said, China's facilities are really quite advanced for a developing country.

Professor Wang Shouguan, director of the Beijing Observatory.

High-level research has been carried out in time-service and positional astronomy where observing equipment is not so expensive and results of practical use can be obtained. Classical optical methods have been improved and China was first to develop an automatic photoelectric version of the Danjon impersonal astrolabe which truly eliminated observer error. Also on the drawing board (and attracting worldwide attention) is a 1.5-m astrometric reflecting telescope for the Shanghai Observatory. This exceptionally large telescope for astrometric work would enable the proper motion of faint stars to be studied photographically.

Much of such classical work is now being supplanted by VLBI and China too

Earthquake prediction

The calm before the storm?

A FEW weeks ago, with reports of the earthquake that killed more than 5,000 people in Mexico City still fresh, Professor Ding Guoyu of the State Seismology Bureau at Beijing confessed himself a worried man. The bureau and its Centre for Analysis and Prediction seems persuaded that there are alternating periods of seismicity (10–12 years long) and of quiescence in the occurrence of major earthquakes in China, and that a new period of activity is about to begin.

Notoriously, the period of the Cultural Revolution was marred by natural disasters, among which earthquakes were prominent, culminating in the loss of 240,000 lives in the earthquake near Tangshan in July 1976. Since then, Professor Ma Zongjim says, there was a period during which earthquakes of magnitude greater than 6.5 on the Richter scale were absent from China until this August's earthquake in Xinjiang province. So now there is a hurry to complete the network of seismic stations being thrown across China under the aegis of the bureau.

The generosity of the government's support for the bureau (with a budget of 100 million yuan a year) is conspicuous. The seismicity of China has two roots, the subduction of oceanic plates beneath the Pacific rim and the stresses and subse-

quent strains of the Earth's crust which are consequences of the collision between India and Asia.

Ding points out that China differs from seismic regions such as Japan in that a large proportion of its earthquakes are within the continental crust (and not buried in some oceanic trench as off the coast of Mexico). That continental earthquakes tend to be exceptionally damaging is easily understood, and is borne out by the evidence that four major earthquakes since 1932 have killed more than 750,000 people.

Accordingly, the plan is to cover China with a network of seismic stations whose function will be systematically to record smaller earthquakes in the hope that these will somehow be pointers (or forerunners of) catastrophe. There are four separate research institutes within the bureau, with its headquarters in Beijing, and a total of 24 provincial seismic bureaux intended to provide operational advice for provincial governments.

Although there are 400 seismic stations of various kinds in China, only 20 are at present equipped with standardized instruments, plus extensometers and tiltmeters. (The stations are also charged with collecting geomagnetic data, raw material for study of the secular variation of the

geomagnetic field.)

Altogether, the bureau has a staff of 5,000 technical people, recruited from university departments of geology and geophysics as well as from its own training school. Its managers say that the network they are developing cannot afford to omit any substantial part of China.

Ma, for example, points out that the earthquake of 1920 which killed 180,000 people had a Richter magnitude of 8.5 and yet occurred in a region which has since been apparently quiescent. It would be dangerous, the argument goes, to neglect such a region simply on the grounds that nothing much has happened in 65 years.

For the time being, the bureau is more an expression of anxiety about a recurring serious problem than a testimony to special Chinese expertise in earthquake prediction. The bureau, originally one of the Chinese Academy's institutes, was made independent on the recommendation of the State Council in 1980. It has to manufacture its own instruments (at a factory near Beijing) and is conscious that these are neither as sensitive nor as accurate as the US instruments being operated at Wuhan under the terms of a collaboration agreement with the United States.

The feasibility of earthquake prediction remains untested. The bureau says that when the immediate task of completing the seismic network is finished, it will try out all possible methods, including the use of accurate triangulation to monitor the movement of active faults. But during the recent quiescent period, the bureau has been looking for trends that may be meaningful in the historical records, which cover the past 2,000 years in reasonable detail.

As the world knows, there is one spectacular success on record for those who would predict earthquakes — the successful prediction of the earthquake near the city of Shenyang in the northern province of Liaoning, abutting the Korean border. This appears to have been an exceptional event, with a whole string of moderately sized earthquakes during the preceding two months converging on what eventually turned out to be the epicentre (see panel on left). Even so, the bureau can and does claim credit for avoiding the loss of more than 100,000 lives.

Just how, and when, the bureau will fulfil its mission of predicting a substantial proportion of the major earthquakes of China remains to be seen. But it works with the Institute of Soil Mechanics (of the Chinese Academy) on the design of buildings that may more adequately withstand major earthquakes. As in other fields, people are eager to learn whatever can be gleaned from other people's experience, to which end no fewer than 20 of the bureau's researchers will be at the forthcoming symposium on prediction, to be part of the annual meeting of the American Geophysical Union next month (December 1985) in San Francisco. □

Portents read in nick of time

THE circumstances of the Shenyang earthquake of January, which eventually was of magnitude 7.0, are unusual to say the least. The Qiang Shan peninsula, which forms the eastern boundary of the Bohai Sea, lies immediately to the east of an active fault running inland towards Shenyang. It is intersected almost at right angles by another, cutting across the base of the peninsula and the broad belt of thick sedimentary deposits supporting, among other things, the valley of the River Hun.

According to Professors Ding and Ma, the most conspicuous of the objective signs of trouble ahead were the small earthquakes preceding the magnitude 7.0 event by as much as two months. There were no fewer than 500 of these premonitory earthquakes in the five days before the major event, all of them within a narrow area centred on the eventual epicentre.

Other objective forewarnings included the variation of water levels in wells and dramatic changes in the output of oil from the oil wells drilled in the neighbouring sedimentary basin, which is a substantial source of petroleum.

There were also reports of strange animal behaviour, including the discovery that overwintering snails that would normally have stayed in hibernation were found to have ventured out and to have

been frozen to death and of deer that broke their legs by jumping fences too high for them. The obvious difficulty is that these abnormal behaviours, if accurately recorded, are as likely to be a consequence of the foreshocks as a sign that animals have a hidden sense of earthquakes on the way.

The Bureau of Seismology does not itself pretend to have an explanation of these phenomena, but says it has asked the Institute of Biophysics (under contract) to look into the question. The institute has a serious interest in neurophysiology, and seems a little sheepish about the whole affair, saying it will have to understand the animal nervous system much more fully before it can give a helpful answer.

No amount of scepticism on these points can rob the seismological bureau of the credit for having predicted an earthquake. But the procedure is far from simple. The bureau says that it does not itself have authority to publish earthquake warnings, only a provincial governor can take that responsibility. In January 1975, the provincial government was persuaded of the significance of the forewarning shocks by 10 a.m. one morning, eighteen hours before the earthquake finally came. It was a narrow squeak not merely for 100,000 people but for the reputations of the provincial government and the bureau. □

Cultural Revolution

True horror stories

ALMOST all those now working as scientists in China are people whose careers were launched before the horror of the Cultural Revolution began. Since the "smashing of the Gang of Four" in 1977, there has only just been time for a trickle of people to work their way through an undergraduate course, and through a PhD course on top of that, so as to become established in a job. The problem of "the missing generation" is apparent, and its implications widely discussed. But what happened to those now at work during that dreadful time? Sheer curiosity impels the question; politeness implies that an answer is usually forthcoming. Here are some case histories.

● One plant scientist spent a year working as a peasant in the fields 200 km away from the laboratory, a further year designing simple experiments to demonstrate the relative benefits of different ways of growing crops and then the whole of two years working on laboratory research with equipment transported from the main laboratory with the help of the "coordinating committee" set up in Guangdong by the provincial government.

● A mathematician (again in Guangdong) who had worked in the field of operational research spent the time of the Cultural Revolution working on the "optimization of industrial production" while travelling around factories in the region.

● An electrical engineer turned high-energy physicist worked on a project for constructing electricity supply lines.

● One mycologist was encouraged to spend several years scouring China for species and strains of soil fungi that might turn out to be sources of previously unknown antibiotics.

● A biochemist was allowed to spend the period of the revolution screening 20,000 people for the presence of alpha-feto-protein in their blood plasma, on the supposition that this might be diagnostic of the liver cancer (linked with hepatitis B infection) which is common along the eastern seaboard of China.

● One of China's most distinguished scientists, Professor Cao Tianqin, president of the Shanghai branch of the Chinese Academy of Sciences who, as director of the Institute of Biochemistry at Shanghai, organized the synthesis of insulin twenty years ago, tells the following horror story, without noticeable anger: "One day, they came and arrested me, my wife and my son. On the second day, they imprisoned me in the basement of the laboratory's animal house: for the next three years, my companions were the rats and the guinea pigs. I didn't see my wife during the whole of that time, and they wouldn't tell me how she was. That was especially worrying because I knew she was due to have an operation for cancer of the breasts. Only

after I was released did I learn that she had survived, but that her recovery from the operation had been very risky because the nurses and the physicians were fighting with each other, and had no time to look after the patients properly."

The moral, for those who would survive cultural revolutions anywhere, seems to be that one should at all costs avoid being a person in authority, for then there is no alternative to being labelled an enemy of the people. Those whose research has obvious practical application may, on the other hand, be able to stay in business. Even those whose research is somewhat academic may be able to persuade the revolutionaries of the opposite; appearances, in China's case, seem to have been more important than substance.

After the event, people seem uniformly to be more amused than offended by their experiences. Some even say that they have never been as healthy, and that it is beneficial that intellectuals should have the experience of working shoulder to shoulder with working people. Those who lost their lives because of the Cultural Revolution, are not available for comment.

Yet people do acknowledge that the ex-

perience of this period may have served some lasting purpose. Many agriculturally oriented research institutes are now more acutely aware of the need for what are called, in the West, extension services. And the notion that researchers should work hand in glove with industry, the cornerstone of China's plan for the future, is in the same spirit.

So may not the Cultural Revolution have been a benefit, after all? Faced with that question, an official of the Chinese Academy of Sciences at Guangzhou blurted out that there is nothing wrong in persuading scientists to work alongside peasants, but that sending researchers to the countryside during the Cultural Revolution was offensive "because the object was to wash our brains".

So will the experiment be repeated, or at least might the present opening to the outside be ended? There are three stock answers. One is that it is too soon to tell. Another is that "objective reality", a Marxist term, not peoples' inclinations will determine what happens in China. Yet another, given with much more enthusiasm in the south than the north, is that the process of unwinding has gone so far in the past eight years that it is no longer possible to turn back.

To outsiders, this absorbing question must still be wide open.

Electronics

Working for industry

THE Institute of Electronic Technology at Guangzhou puts out an advertisement to attract industrial partners that concludes with the exhortation "visit round our institute and have a promising business with us". The message is seriously meant and appears to be have been remarkably successful. In September, the institute was boasting that it had been able to sell a software package for the computer manipulation of Chinese characters to a commercial company in Hong Kong for HK\$100,000. One of these days, the product may appear in a Chinese word processor being developed by the Tensing Microprocessor Company, registered in Hong Kong.

The institute is also proud of its origins as a comprehensive research institute established by the provincial government in 1970, when China was in the grip of the Cultural Revolution. Then, it seems, the Guangdong government set up an organization to monitor the effect of the revolution on the infrastructure of its own operations, which is another mark of the sense of independence that flourishes in the south.

The institute became one of those belonging to the Chinese Academy of Sciences only in 1978, with a general remit to develop the techniques of telecommunications and of the applications of computers in this and other fields. With the general

adoption of the policy that government institutes must collaborate closely with industry, the institute has set up a commercial company, the Ling Nan Scientific and Technical Development Company, specifically so as to promote the transfer of technology developed at the institute as well as to provide design and computing services for industrial enterprises in China and elsewhere.

Inevitably, an institute in the field of electronics with Hong Kong on its doorstep must be growing quickly. There are now 400 people at the laboratory, four times as many as at the beginning. Since the institute's incorporation within the Chinese Academy network, much of its work has been stimulated by projects mounted on a national scale by the Academy. Thus the institute is the designer and has become the constructor of the telemetry packages used in the now extensive Chinese programme of balloon-borne physics, the cosmic-ray programme run by the Beijing Institute of High-Energy Physics, for example. Here, as in many other fields, the Chinese have taken great care that they will be able to recover in repairable form any equipment whose construction has been difficult and expensive. This same interest explains why the Guangzhou institute was chosen to build the telemetry and ground station equipment for an astronomy satellite being built by the

Academy institutes, but for which the launching plans are not yet known.

The institute is well along the road the Academy wants as many as possible to follow, that leading to close partnership with industry. Vice-director Chen Yan-yi says that dependence on central funds has declined from 90 per cent of the total budget in 1978 to just about a half now.

For the future, the institute expects that

it will be able to continue growing. Among other things, it is working with the regional government on schemes for the fuller application of microprocessors, not merely within the provincial government's sphere of operations but in Guangdong industry. Hong Kong's influence reaches beyond the special economic zone to the Pearl River, it appears. But the electronic technology institute still has a homespun

air. In a ground-floor laboratory, Wu Caiqing, manager of what is called the Chemical Arts Department of the Ling Nan company, uses what is described as a secret formula to produce etching-like patterns with artistic pretensions on the surfaces of useful and decorative objects of various kinds. Which only goes to show that, in the south, all ways of turning an honest penny are embraced. □

Science popularization

A CAST of thousands

WITH more than a million members, the Chinese Association for Science and Technology (CAST) is beginning to make a mark on the scientific scene. CAST is the umbrella organization for all of China's specialist scientific and technological societies or, as the Chinese would say, it is "a mass multidisciplinary organization of workers in science and technology". The association has only recently re-built its strength after being out of operation throughout the Cultural Revolution.

Those who have attended a conference in China will probably already know CAST for it plays a major role in organizing international exchange. Indeed, the dollars earned from visitors are all ready to help Chinese scientists abroad (when the ministry of finance eases its foreign currency restrictions).

But organizing conferences is only part of CAST's work. Its influence is now felt both by the government and the people. CAST regularly sends its policy recommendations, drawn up by specialist committees from its member societies to Party and government, and at the ministry's request gives technical advice.

CAST also spreads its roots down into local science and technology associations set up to bring science to ordinary peasants and workers. During the Cultural Revolution, there was little opportunity of learning about scientific ideas and CAST itself was disbanded — not until 1980 was it able to hold a national meeting again. But now the press is full of articles about peasants who made fortunes by increasing productivity through application of a little science. Some have achieved virtual stardom: like the chicken raiser in Heilongjiang Province who made so much money that she has been able to build a fifteen-room mansion. CAST is now out in force to take learning into the countryside.

Some campaigns are conducted on an awesome scale. Last year, in Hubei province, 20,000 CAST members went out and gave 80,000 workshops for middle school graduates from farming families — the total audience was five million people.

Keeping up the pace are numerous small scientific associations. At the county level its chief members are likely to be the local doctors, middle-school teachers and technicians from the bureau of agricul-

ture. (Such local improvement societies find their parallel in Victorian England.) Down at the village level (a level of organization formerly occupied by the commune) members will be those who have acquired some special technical skill, say in agriculture or cultivation of fruit trees. Some of their free time is spent in seeing their expertise disseminated. Local halls will be hired for lectures and on a market day a stand may be set up where villagers can learn about improved agricultural techniques.

There are nearly 2,200 science and technology associations at the county level, representing 93 per cent of China's coun-

ties. Some are even able to afford a few full time administrative staff. Down at village and commune level there are 41,000 sub-branches.

CAST does not actually control these lower-level organizations; they are all independent. What CAST does is to prepare publicity material, posters and books, provide speakers from its member societies and help coordinate national campaigns.

On a national scale CAST reaches a massive audience through magazines and books produced by its Science Popularization Press. And for children, there are science summer camps, "love science" campaigns aimed at encouraging kids to read scientific books, fairs showing scientific work by children and a national competition for child inventors. □

Some of the magazines produced by CAST's Science Popularization Press have circulations around ten million. The magazine Knowledge is Power (centre) carries some articles close to science fiction — like "Can man live for ever" and "Using hypnosis to stimulate creativity" — but the majority are educational: how electronic devices work; nutrient cycles on Earth, elementary BASIC and the like. Shown behind are regional science and technology newspapers with a more practical bent. They carry articles on such topics as new breeds of fish, forestry policy, how to produce carbon black, and the cross breeding of livestock. Alongside come some features designed to encourage: one story is of a 22 year old high school drop out who develops a new tea variety called "Rainbow" and lands a 7,000 yuan contract.

Aggregation by very large numbers

Computer models of aggregating systems have thrown a useful light on physical processes in the past few years. But too much computer power may make them more intricate than instructive.

THE neater the model, the more easily it is elaborated, and made complicated. That simple truth, always apparent, has been more evident than ever since computer power became more easily and cheaply available. The model of simple harmonic motion represented by the idealized simple pendulum could, no doubt, be made too complicated for a Cray computer to handle by the wooden elaboration of enough complexity.

Much the same, it seems, is now happening to the simple model of diffusion-limited aggregation first put forward four years ago by T. Witten and L.M. Sander (*Phys. Rev. Lett.* **47**, 1400; 1981). The original idea was simple, that of constructing a model to account for processes such as crystal growth whose rate is determined by the diffusion of aggregating particles through solution towards the growing crystal.

The simple version of the model is that in which aggregation takes place on a two-dimensional lattice. Particles are allowed to "diffuse" from the periphery of a piece of the lattice towards a central point by supposing that they move randomly, one lattice step at a time. It is necessary to specify the set of rules that determine when a particle will stick to the growing aggregate; most simply, it can be required to stay where it is whenever it reaches a lattice-site that is immediately adjacent to one already occupied.

Several important demonstrations have been possible with this simple, almost crude, model. Not least, for example, it turns out that aggregates constructed in this way are fractal structures; the numbers of particles they contain increase monotonically with increasing radius, but by some power of the radius which is less than 2.0, the value expected for a structure filling all the dimensions available in a plane. The value of the exponent in the power law with radius is now the familiar fractional dimension. The fact that just such behaviour is observed when dendritic solid structures grow from, say, solution, or when ice crystals form from the vapour, justifies the wide use made of the model and its elaborations in the past few years.

One side benefit of this simple model is that it lends itself easily to computer calculations. Tell the machine the rules, and it will replicate them indefinitely. So it has come about that a small army of ingenious people has been trying variants of the Witten-Sanders model. More than two

dimensions? No problem, except for the cost of computer time. What is the rate at which smaller aggregates will stick together to form larger structures? Again there is no problem once the rules are specified. The fact that the Witten-Sanders model also serves to account for phenomena other than diffusion-limited aggregation, percolation for example, has made it even more popular.

Naturally, there has been a great deal of interest in attempts to make the model realistic. Obviously, in a model growing by random aggregation, there is a possibility that loops will form between one part of the structure and another, thus excluding a large part of the accessible space from occupation. Are these physically realistic conditions, or should they be excluded as rare configurations with extraordinary implications?

Then the simplest set of rules, requiring that particles should stick to an aggregate whenever they reach a neighbouring site, makes no allowance for the likelihood that different sites might be occupied with different affinity. That is why some investigators have set out to calculate the probability that various sites will be occupied by running the random walk backwards.

More recently, attempts have been made to construct still more realistic models of aggregation by changing the rules, allowing a particle either to stick at the first nearest-neighbour site it reaches or, alternatively, to move to a neighbouring occupiable site, perhaps because such a site may be energetically more favourable. (Two neighbours are better than one.) There are reasons to suppose that the results of such calculations may enjoy a degree of realism (see P. Meakin and R. Jullien, *J. Phys.* **46**, 1543, 1985).

The most recent development is an attempt to construct a kind of equilibrium model of aggregation. The idea (due to R. Botet and R. Jullien of the University of Paris-Sud (*Phys. Rev. Lett.* **55**, 1943; 1985) is to begin with an aggregate of some kind and arrange that particles may escape from peripheral sites with single nearest neighbours, wander about by random walking (again on a two-dimensional lattice) and then stick to an aggregation site when next they reach it. If the wandering particle should get too far away, say to the circumference of a distant circle, it will be captured and released again at a random point.

Technically, there is no doubt that the

aggregating particle is stable. The number of particles is essentially constant; the rules specify that there can never be more than one particle on its travels. So what do the calculations show about the way in which the shapes of aggregates change with the repeated release and recapture of particles at the periphery?

First, for a specified number of particles in the initial aggregate, there is a final state with recognizable characteristics determined only by the number. For example, starting with a cluster of 100 particles allowed to randomize themselves by these formal rules, Botet and Jullien show that the radius of gyration of the end result is roughly eight unit lattice spaces. Attenuated structures (say, a string of 100 particles in a straight line) will finish up as a spindly structure. So too will structures that begin as compact clusters, with no spaces between occupied sites.

The obvious disappointment is that the model, as specified, is not a model for aggregates in equilibrium, but instead a model for an aggregate whose size has been arbitrarily fixed. Put simply, it is a model that presupposes that disaggregation is not an option for the system, or that the energy of the attachment of particles to aggregate is infinite. In the circumstances, especially because there can be no attempt to distinguish between the probability with which different kinds of clusters can occur, which is the same as saying that the energy of all configurations is the same. In other words, the model is a long way from being a model of equilibrium aggregation.

That does not, of course, imply that the calculations are without interest. But it is not surprising that the fractal dimensions of aggregates held constant under these conditions should be less than those of the aggregates formed in the first place by the Witten-Sanders process (1.54 against 1.70). Nor is it remarkable that some configurations built from very small aggregates (of, say, eight particles) should occur less frequently than sheer chance dictates. The promised calculation of what happens when larger aggregates split in two, by the severance of a bond chosen at random, may however be more directly relevant to speculation about the way in which aggregates rearrange themselves. The pity is that, for the time being, there are no usable analytical methods of making progress with these problems.

John Maddox

Epstein–Barr virus

Dream or reality of a vaccine?

from A.J. Beale

EPSTEIN–BARR virus (EBV) was first recognized in cultures of Burkitt's lymphoma cells and is a member of the herpes virus family. It was soon established as a cause of infective mononucleosis. There has also been a strong association between the virus, Burkitt's lymphoma and nasopharyngeal carcinoma. Since 1976, Epstein and his colleagues have mounted a systematic search for a vaccine against the virus in the hope that the viral aetiology of the two malignancies could be proved, with much benefit to high-risk populations in Africa, China and South-East Asia. Their studies have reached another landmark, as described on page 287 of this issue of *Nature*.

Epstein *et al.* have previously identified as a candidate immunogen an EBV glycoprotein termed gp340, and have devised means for its extraction, techniques for measurement of both gp340 and antibodies to it, and have developed an animal model of EBV-induced lymphomas in cottontop tamarins (*Saguinus oedipus oedipus*). The stage was set for the critical experiment in which vaccinated and unvaccinated tamarins were challenged with EBV. This experiment and the success of the immunization is now reported.

As the test vaccine, gp340 preparations, containing a minimal amount of residual living virus, were given to two tamarins in eight intraperitoneal doses at fortnightly intervals. Both animals developed antibodies that could be detected by an enzyme-linked immunosorbent assay, by immunofluorescence and by neutralization of EBV transformation of cord blood cells. They were both protected against a massive challenge dose of virus which caused disease and multiple tumours in control animals. Isolated gp340 in liposomes was less immunogenic than the membrane preparation: in a group of four animals given this vaccine, only one produced high concentrations of antibodies and was protected against viral challenge. Thereafter, two animals were given 17 intraperitoneal doses of the liposome preparation at fortnightly intervals and were subsequently challenged. Both animals developed transient inguinal lymph node enlargement after challenge; in one case this was accompanied by transient mesenteric node enlargement.

From the successful development of a vaccine against Marek's disease, to which fowl are particularly prone, it is already clear that a vaccine against tumours caused by herpes viruses is feasible, and the work now being reported on EBV shows that the development of a similar vaccine for a human herpes virus is theoretically possible. Is it likely to be a practical

proposition to make and test such a vaccine? The candidate vaccines of Epstein *et al.* are not practical: clearly, the membrane preparation of gp340 would need rigorous testing to show it was free of infectious virus before its use in man could be contemplated, and either vaccine would need to be presented in such a way that a protective immune response is achieved with fewer doses of vaccine. Doubtless the schedule could be improved to ensure priming and the elicitation of a secondary response.

The most important advance referred to by Epstein and his colleagues is the cloning and sequencing of EBV and identification of the sequences encoding gp340. It should therefore be possible to produce the protein in large quantities. Since it is glycosylated — more than 50 per cent of the mass is carbohydrate — it may prove best to prepare it in mammalian cells, as is done for many other viral immunogens, rather than in bacteria or yeast. Alternatively it could be expressed in vaccinia virus or some other carrier. The groundwork for developing a vaccine against EBV seems to have been soundly laid and the technology to produce sufficient immunogen is at hand.

The major problems of organizing and financing the procurement and testing of such a vaccine remain to be solved. The problems of organizing trials against diseases caused by EBV are formidable, even when compared with other herpes

virus infections. Whereas infectious mononucleosis is an early manifestation of primary infection, Burkitt's lymphoma and nasopharyngeal carcinoma are late manifestations that often take many decades to emerge. No one knows at present whether the late manifestations can be prevented after infection, but current opinion is sceptical. The aim, therefore, must be to prevent infection.

Trials of a vaccine against infectious mononucleosis are a practical and worthwhile proposition, given the will, in Western countries. Proof that EBV infection and this disease can be prevented by a vaccine would warrant the use of a vaccine to prevent Burkitt's lymphoma and nasopharyngeal carcinoma. It is doubtful whether it is practical to carry out a placebo-controlled trial lasting decades, but observation of the effect of vaccine on disease together with more limited trials of the vaccine on viral infections may suffice to demonstrate that EBV is indeed the cause of Burkitt's lymphoma and nasopharyngeal carcinoma.

For a number of diseases, ranging from malaria and pertussis to those caused by hepatitis B and EB viruses, there are now prospects for control by immunization, based on a molecular understanding of the immunogen required to produce protection. To harness this promise, a more determined and imaginative approach to preventive medicine and public health is required. Provided government agencies can see the economic as well as the health benefits of developing such approaches, the benefits to mankind and human health could be immense. □

γ-ray sources

Does Geminga exist yet?

from Roger W. Romani and Virginia Trimble

THE peculiar γ-ray source in the constellation Gemini, termed Geminga, is once again puzzling astronomers. Originally found by the SAS-2 satellite¹ and later studied by γ-ray detectors both in space² and on Earth³, this object presents strange features in every wavelength band. One of the strangest — that it cannot be detected at visible and radio wavelengths — is reflected in its name, which also means "does not exist" or "is not there" in Milanese dialect. New optical observations (refs 4–6 and G.F. Bignami *et al.*, in preparation) have provided a tentative identification but these make Geminga seem even more inexplicable: as G.F. Bignami (Milan) reported at a recent meeting*, the object is exceedingly faint and

may have a very large proper motion.

As the brightest of the 20 unidentified γ-ray sources in the COS-B catalogue², Geminga is a natural subject of searches for corresponding sources in other energy ranges. The high count rate and large distance from the confusion at the galactic centre allowed the COS-B collaboration to obtain a position that is excellent by γ-ray standards. Images taken with the Einstein X-ray satellite's high resolution imager (HRI) and imaging proportional counter (IPC) led to the identification of Geminga with the bright source 1E0630+178 (ref. 7), supported, it then seemed, by the same 59–60-second, gradually lengthening pulse period in both X- and γ-ray data⁸. Buccheri *et al.*⁹ and others have doubted the periodicity, without necessarily disbelieving the identification, because there is unlikely to be an unusual

*NATO Advanced Study Institute on "High Energy Phenomena around Compact Stars" held at Cargèse, Corsica, 2–13 September, 1985.

X-ray source and a bright γ -ray source in one 0.4 square degrees of sky.

Searching at lower frequencies and with greater positional accuracies has met with some difficulty. Radio maps of the γ -ray error box (refs 10–12 and V. Boriakoff *et al.*, unpublished data) reveal more than a dozen 10–100 mJy sources, but there is nothing at the X-ray position and nothing particularly unusual anywhere.

At optical wavelengths, deep charge-coupled device exposures taken at the Canada–France–Hawaii telescope in January 1984 revealed a 21st magnitude image marginally within the Einstein error circle¹³. Dubbed the G candidate, it has been closely scrutinized by a number of groups. Discouragingly, optical and infrared photometry and spectroscopy (refs 4, 5, 14, 15 and M.J. Lebofsky, unpublished data) indicate that the candidate probably is just a G-type star — a cool white dwarf 100–200 pc from us or, more likely, a slightly hotter main-sequence or subdwarf star several thousand parsecs away. Both are inconsistent with the Einstein X-ray colour temperature of about 10^6 K (ref. 7) and the latter is also inconsistent with the very low X-ray absorption ($\leq 2 \times 10^{20}$ H cm⁻²), which indicates a distance less than 250 pc.

Moreover, a careful search for optical pulsations at a range of periods around those reported in X and γ -rays⁵, has set 2–4 per cent limits on any variability of the G candidate. The sky, according to Lebofsky, is full of similar stars and the chances of this one having anything to do with Geminga are slim.

Meanwhile, back at Lick Observatory, Djorgovski and Kulkarni⁴ have searched deeper at the HRI position and found two fainter candidates: G' at 24.5 mag near the centre of the error circle and G'' at 25½–26 mag off to one side. The lack of any brighter optical counterpart has interesting implications for 1E0630+178. The ratio of X-ray to optical luminosity is about 1,000 if G' is the counterpart, 2,500 if G'', and $\leq 3,000$ if neither is — among identified Einstein sources, only the radio pulsars and low-mass X-ray binaries have such large ratios. The absence of a detectable radio signal argues against a radio pulsar and the faintness of G' would place a typical X-ray binary at the improbable distance of 200,000 pc, arguing against an X-ray binary. This makes 1E0630+178 unlike any other known X-ray source, whatever association it has with Geminga.

G' and/or G'' seem to be peculiar, in any case. Djorgovski and Kulkarni⁴ report that G' has a tentative proper motion of 0.6 seconds per year; an alternative explanation is that this reflects a larger motion of G'' plus spillover of light between the images. In addition, the image that Bignami and his collaborators have obtained by summing the twelve exposures made in January 1984 shows a faint object that could be G''. But its position is very different from that found at Lick in

March 1985, implying a proper motion of 1.4 seconds per year for G'' and an upper limit of ≤ 0.2 seconds per year for G'.

Its rapid motion, if confirmed, must place the star quite close to us; for example, even a halo object moving at 200 km s⁻¹ would be no more than 30 pc away. What could it be? From the magnitudes, G' and G'' could be interpreted as brown dwarfs, not unlike the recently-discovered companion of ν B8 (ref. 16). But such a star is most unlikely to be either the X-ray source or a chance superposition; if there were a single brown dwarf so close to us in every 10⁵ Einstein error circles ($r = 3.3''$), it would make up the entire local 'missing mass' and can therefore be excluded from searches of larger areas.

It is somewhat more likely that G' or G'' is the thermal emission from a neutron star. Because the optical effective temperature could be anywhere from the X-ray colour temperature (10^6 K at the hot polar caps) to the X-ray effective temperature ($\sim 3 \times 10^5$ K), the implied distance is quite uncertain. Possible combinations are G'' with the lower temperature and a runaway velocity of about 200 km s⁻¹ at 20–30 pc, or G' with the higher temperature and atypical young star velocity of ≤ 50 km s⁻¹ at 80–100 pc.

Not even a white-dwarf binary companion^{17,18} could remain hidden at these distances, which leaves only binary¹⁹ or single²⁰ neutron stars as viable models. Either is possible in energetic terms, if the 60-second period is real and can be attributed to orbital motion or rotation in the two cases, although this then means γ rays must be grossly non-thermal. But both models imply soberingly short lifetimes, about 700 years, and the second may also

have difficulties in explaining the acceleration of particles to the energies needed to emit γ rays. The short lifetime would make sense if the 'guest star' of +437 gave birth to Geminga⁸ but the total absence of emission nebulosity in the vicinity argues against any recent local violence.

Clearly, one or two more deep images of the region, confirming or refuting the rapid motion of G'' and providing a bit of colour (temperature) information on the two candidates, will be critical for sorting out the confusion, in which Geminga, 1E0630+178 and G' or G'' could be one, two or three interesting objects.

Plant sciences

Molecular view of pollen rejection

from Deborah Charlesworth

IN MANY species of flowering plants, a genetic self-incompatibility mechanism causes the rejection of pollen from the same plant. The genetic control is determined by one or more self-incompatibility (S) loci and it has been clear for several years that many of the mysteries surrounding the S locus will be resolved only when the molecular structure of the locus is known. A start in that direction is provided by J.B. Nasrallah and colleagues on page 263 of this issue¹.

Two types of self-incompatibility are known². In the Compositae and Cruciferae, and perhaps also in some other families^{3,4}, control of the pollen reaction is sporophytic — that is, the pollen type is determined by the genotype of the plant that has produced it — and there is usually, perhaps invariably, a single S locus. In gametophytic systems, which are known in several families and where the pollen

type is controlled by the alleles in the pollen grains, there is often one but may be two S loci, as in the grasses, or even more; *Beta vulgaris* has four⁵. With both types of system, there are very large numbers of alleles at the S loci, so that although the genetic data indicate that the S loci control the specificity of the reactions, which must be expressed both in pollen and in the stigma or style in order for self-incompatibility to result, there has been a recurring tendency to doubt whether the sequence information for all the S glycoproteins is really encoded at the S locus, and to suggest that some or all of it must exist elsewhere in the genome, and that the S locus somehow switches between specificities^{6,7}.

Nasrallah *et al.* already have some data relevant to this question. They have cloned DNA from the S₆ allele of *Brassica oleracea* and shown that the protein encoded by the S DNA is detected by an

antibody to the S_n glycoprotein produced in intact stigmas. Thus the S locus must contain the sequence that encodes the S_n glycoprotein, although it remains possible that other loci also contain S DNA sequences. A test of that possibility will be to determine whether all clones isolated from a given homozygous genotype contain the same DNA sequences, which would suggest that they are all derived from a single locus. Alternatively, the clones may reveal the presence of multiple self-incompatibility loci, even if they are very tightly linked. Nasrallah *et al.* have probed digests of the genomic DNA of homozygous lines with several S alleles with their S_n probe; although so far they have only used a single restriction enzyme, each allele has been shown to give a unique pattern, and the variation suggests multiple differences will be revealed by the use of further restriction enzymes. On the other hand, the results provide preliminary evidence suggesting that there is only a single locus; if there were many loci, one would expect to see a complex pattern of many bands, varying in intensity as well as mobility.

Another very important question that can now be studied is whether the S specificity is determined by the protein or the carbohydrate part of the molecule. The high number of S alleles in self-incompatible plant species makes it hard to imagine that the carbohydrate part alone could be responsible. Now that the DNA can be obtained, it will be easy to see how much the amino-acid sequences of the S proteins differ, and whether this variation is in the position and nature of attachment sites for the carbohydrates. Ultimately, it should be possible to look for regions concerned with the different functions of the S protein. At present, it is not even clear whether the three functions of specificity, and activity in the pollen and stigma or style are controlled by three separate, but tightly linked cistrons, as suggested by Lewis⁸ on the grounds that the three functions are independently alterable by mutation, or whether they could be under the control of a single locus with separate functional domains. Nor do we know whether the antigenic specificities used in detecting S proteins have anything to do with the regions that are important for the plants' recognition reactions.

A related puzzle is that apparently mutations of one S allele to another do not occur⁹. Except during another culture¹⁰, such changes have so far been detected only under conditions of inbreeding^{11,12}, thus if anything deepening the mystery. Since S loci are highly polymorphic, in all species where any relevant data exist, mutation must occur to balance chance loss of alleles. The rarity of S mutations might be because existing S alleles differ at multiple amino-acid sites. Assuming that only a subset of possible sequences of the S protein can function as self-incompatibility alleles, one would not be able to get

mutation from one S allele to another, but could get mutant types that lose the ability to be processed in pollen or style (as in Lewis's pollen-part and stylar-part mutations). Molecular studies should help to test these ideas, and should suggest why mutations are so rare.

Once the S gene is characterized in one species, it will be possible to probe for the S genes of related species, which will be of great practical significance. Indeed, it may be the best way of genotyping plants for the S locus, given the difficulty of genetic methods of testing and the uncertain success of techniques using the proteins, such as immunological methods^{13,17}.

Eventually, this type of work should enable us to determine whether S loci in different families of plants are homologous. The S DNA isolated by Nasrallah *et al.* will be useful with other sporophytic systems, but one can hope that DNA from species with gametophytic systems will be isolated in the future. It may then be possible to find out whether S systems are homologous in all angiosperms¹⁸, or have

evolved more than once, as seems likely from the distribution of the different types of system¹⁹. □

Petroleum geochemistry

Advance in kerogen analysis

from R.P. Philp

It is commonly accepted that kerogen is a key intermediate in the formation of crude oil and/or natural gas from the organic debris of algae, bacteria, higher plants and other sources. Kerogen (Greek = oil or wax forming) is best described as the insoluble organic residue that remains after the organic solvent-soluble material, carbonates and silicates have been removed from the source rock or shale. Kerogen itself is formed following a series of complex chemical and, probably, microbial reactions involving the organic debris of higher plants, animals, algae, bacteria, spores, fungi, phytoplankton and zooplankton that is deposited in aquatic and reducing environments which favour the maximum preservation of organic material. Information on the nature of the organic source material responsible for its formation, its structure, the type of fossil-fuel products it will yield and its relative level of maturity is extremely important for petroleum exploration purposes. The paper by S.R. Larter and J.T. Senftle on page 277 of this issue reports a significant advance in the use of microscale pyrolysis techniques combined with gas chromatography (py-GC) for obtaining such data.

Most of the data used in oil exploration are based on analysis of oils and the soluble fractions of rocks. The kerogen in rock can be thought of as being indigenous, whereas it is always possible that the soluble fraction has migrated through the rock. The bulk of kerogen in source rocks and shales is insoluble in virtually all organic solvents and thus more difficult or

impossible to analyse by conventional methods such as gas chromatography (GC) or gas chromatography-mass spectrometry (GC-MS).

Microscale pyrolysis combined with GC and/or GC-MS provides a very powerful technique for kerogen characterization because a great deal of the geochemical data locked into the insoluble structure of kerogen can be released. Subsequent analysis of the pyrolysis products by GC provides information on the source material, thermal history and type of liquid products their host rock can generate. Another major advantage over analysis of the soluble material from the same rock is that all contaminants are normally removed during isolation of the kerogen, before characterization by py-GC. A major significance of Larter and Senftle's work is that it is a first attempt to quantify py-GC data for application to geochemistry. Equally important is the recognition of eight separate modes of kerogen composition from a number of cross plots involving normal hydrocarbon, aromatic hydrocarbon and total hydrocarbon yields obtained from the characterization of the kerogens by py-GC.

The word pyrolysis has been used in the geochemical literature to describe many different types of experiments, which has led to some confusion, to say the least. This is not the place to attempt a detailed classification but one broad distinction that needs to be made is between hydrous and anhydrous pyrolysis experiments. The work of M.D. Lewan *et al.* (*Science*

203, 897; 1979) greatly stimulated the use of hydrous pyrolysis techniques for evaluating the oil-generating potential of the source rocks from a particular basin. In this approach the source rock is sealed in a high pressure bomb with an appropriate amount of water and heated for varying periods at different temperatures. Obviously, water is not added to anhydrous experiments, but because crushed source rocks are very rarely completely free of water, it is doubtful if such experiments are ever truly anhydrous unless special conditions are observed.

Because of the apparent lack of alkenes in the products, the hydrous technique was promoted as the only method that could truly simulate the generation of crude oils in the laboratory, but it is more correctly thought of as a thermal simulation experiment in a closed system. In this situation, alkenes are unstable and are either transformed to saturated forms or react with the organic matrix. Evidence is, however, now available to show that alkenes can be generated under certain conditions of hydrous pyrolysis and their generation can be eliminated under certain conditions of anhydrous pyrolysis.

The most useful applications of hydrous pyrolysis are to simulate the effects of natural maturation in the laboratory and to determine the petroleum potential of a particular stratigraphic sequence at different burial depths within a basin. With one exception, the main application of anhydrous pyrolysis in geochemistry has been for typing kerogens and their possible precursors to determine the nature of the products that would result from the additional maturation or burial of the kerogen. The exception is the widely used Rock Eval pyrolysis method, widely used in the petroleum industry for routine and rapid screening of samples as they are recovered during the drilling of a well. In this method a crushed rock sample is subjected to a temperature range from ambient to 550° and the products analysed using a flame-ionization detector. Two chromatographic peaks are observed, the first relating to material normally extracted by solvents, the second to the products of thermal degradation of the kerogen. The temperature at which the second peak maximizes can be related to the maturity of the sample, and ratios of the two peaks provide information on the petroleum potential of a source rock.

Larter and Senftle report an advance in the technique of anhydrous pyrolysis, which commonly involves the combination of the pyrolysis system with either GC or GC-MS and permits fingerprinting of kerogens on the basis of the distribution of their pyrolysis products. (Although alkenes are produced during the pyrolysis reaction, this should not be looked on as a detrimental feature of the technique because alkenes still represent structural features of the kerogens which, in the natural situation, would be hydrogenated to the

corresponding alkane.) Larter and Senftle now describe how the use of polymethylstyrene as an internal standard permits the accurate quantitation of pyrolysis yields. The advantage of this approach is illustrated where two quite different macerals produce pyrograms that are indistinguishable from a qualitative point of view but can be differentiated by quantifying the yields of pyrolysis products. The study also shows that cross plots of the $C_7 - C_{25}$ normal hydrocarbons versus the $C_6 - C_8$ aromatics permit the different types of kerogens to be clearly observed. A further level of differentiation is obtained by plotting $C_9 - C_{30}$ normal hydrocarbon concentration versus the hydrogen index from the Rock Eval data (equivalent to H/C ratio), which in turn permits the differentiation of eight types of kerogen.

The past five years have seen tremend-

ous developments in the application of geochemistry to petroleum exploration in areas such as oil/oil and oil/source correlations, maturity, migration, source determination and basin modelling studies. Much of this has been based on solvent-extractable organic compounds. The next five years will see a similar expansion using of information from py-GC characterization of kerogens, together with partially insoluble material of high molecular weight, the asphaltenes. Microscale pyrolysis will be a key to eliminating confusion arising from the use of the soluble fraction; the quantitation described by Larter and Senftle will be valuable for the technique's continuing success. □

Molecular evolution

The uniqueness of Archaeobacteria

from Roger A. Garrett

UNTIL recently, orders of unusual microorganisms that had adapted to a peculiar niche, or exhibited a biochemical oddity, were considered to be subdivisions of the prokaryotes. Superficially, this classification was tenable. But once genetic information, or nucleotide sequences, of the microorganisms were examined closely, some species were revealed to be as different from the other prokaryotes, or eubacteria, as they are from the eukaryotes. Consequently these organisms have been classified by Carl Woese and colleagues (*Science* 209, 457; 1980) as a third primary kingdom, the Archaeobacteria. Despite the evidence of their nucleotide sequences and several distinctive biochemical characteristics, this assignment has received a sceptical response from some quarters, but the participants of a workshop on the molecular biology of the archaeobacteria* should have been convinced by the plethora of unusual and unexpected characteristics reported.

The unique features of the nucleotide sequences have been demonstrated by Woese and colleagues for the 16S-like RNA molecule from the smaller of the two ribosomal subunits. They chose this molecule for at least two reasons: it occurs in every living organism and its functional role in protein biosynthesis has remained constant throughout evolution. Moreover, in the cytoplasmic ribosomes of eukaryotes, although its size increases substantially it retains the core structure common to the prokaryotic RNAs. Comparison of partial and later of whole RNA sequences produced coefficients for the degree of relatedness between organisms. It was these coefficients that first revealed

the deep divide amongst the prokaryotes.

This division quickly received support from biochemical studies. The membrane lipids of the archaeobacteria were shown to have ether-linked and branched aliphatic chains, whereas those of eubacteria contain ester-linked and straight aliphatic chains. Moreover, the DNA-dependent RNA polymerases from archaeobacteria yielded more complex subunit patterns than those of eubacteria.

The archaeobacteria consist of three main orders: the extreme halophiles, the methanogens that metabolize carbon dioxide to produce methane, and the sulphur-dependent extreme thermophiles that include the Thermoproteales (comprising the families Thermoproteaceae, Desulfurococcaceae, Thermofilaceae and Thermococcaceae) and the Sulfolobales that grow under very acidic conditions; only the species *Thermoplasma* does not fall into any of these orders but occupies an intermediate position. Each order has some special characteristics that reflect adaptation to a particular niche, as exemplified by the heat-stable RNA structure in the extreme thermophiles, but other characteristics are common to all archaeobacteria.

Among the archaeobacterial characteristics reported at the workshop were uniquely modified nucleotides in tRNAs, unique features of the secondary structures of each of the ribosomal RNAs, different ribosome shapes and sensitivities to antibiotics, DNA-dependent RNA-polymerase subunits that seem to be like those of eukaryotes, unique reverse gyrase that produce positive super-coils in closed circular DNA and nucleosome-like structures; there was also evidence of unusual modes of gene transfer.

*EMBO Workshop "Molecular Genetics of Archaeobacteria", Martinsried, West Germany, 23-25 June, 1985.

The instability of the genome of *Halobacterium halobium* and of closely related halophiles received special attention. Recent studies of its chromosomal organization and of various extra-chromosomal elements (W. Goebel, University of Würzburg; and F. Pfeifer, University of California, San Francisco) shed some light on the structural basis of the instability. The main chromosomal fraction, FI DNA, is 68% G+C-rich and can be readily separated from the more A+T-rich FII DNA fraction. The latter is complex and contains a heterogeneous collection of covalently closed circular DNAs, including a large plasmid carrying many insertion elements, as well as various minor components. Also present in the FII DNA are non-circular 70 kilobase (kb) 'islands' that probably associate with the chromosomal FI DNA; these also contain inser-

tion elements and participate in the genetic variation. A phage, ϕ H, isolated from the halophiles, also exhibits a high degree of genetic variability. No conclusive explanation was offered for the functional significance of the lability of the *H. halobium* genome, although some genomic changes seem to be reversibly inducible by changes in external salt concentration.

Exciting developments were reported in the characterization of virus-host systems (W. Zillig, Max-Planck-Institut für Biochemie, Martinsried) that will prove valuable in future for investigating the molecular genetics of the archaeobacteria. They included the nucleotide sequence of the virus-like SSVI from *Sulfolobus solfataricus* that has a 16-kb genome, and the identification of four viruses from *Thermoproteus tenax*, that partially resemble eukaryotic viruses in their structural orga-

nization. The ϕ H phage and the plasmid pSL10 from *S. ambivalens* are especially suited to vector development; other potentially important phage and plasmid vector systems were described for the methanogens.

The regulation of gene expression also figured prominently, with emphasis on the more readily isolated rRNA and tRNA genes and the bacterio-opsin gene of *H. halobium*. The observation of multiple transcriptional starts for the single rRNA operon of *H. cutirubrum*, occurring at regularly repeated sequences that include the motif 5'-A-A-G-T-A-A-3', was unexpected (P. Dennis, University of British Columbia, Vancouver). Another putative promoter sequence 5'-G-A-A-N-T-T-T-C-A-3' was deduced from sequencing the *purE*, *proC*, *hisA* and *argG* genes of various methanogens expressed in *Escherichia coli* (J. Reeve, Ohio State University, Columbus). Termination sites are less easily found; although some potential signals resemble those of eubacteria, others do not — it was suggested that five consecutive thymidines might be sufficient for ending the methyl-CoM-reductase gene of *Methanococcus voltae* (A. Klein, Phillips University, Marburg).

The detection of introns among the extreme halophiles and in a thermoproteale was a surprise. A 105-bp intron has been found in the tRNA^{Trp} gene of *H. volcanii* and other halophiles, with a fairly well-conserved sequence (C. Daniels and W. Doolittle, Dalhousie University, Halifax). Moreover, a 622-bp intron containing an open reading frame has been located in the 23S rRNA gene of *Desulfurococcus mobilis* (J. Kjems and R. Garrett *Nature*, in the press) in a similar position to that of an intron in the corresponding gene of the lower eukaryote *Physarum polycephalum*. Although no introns have been reported for protein messenger RNAs, the new results, together with an earlier report of putative small introns in the tRNAs of the sulfolobales, suggest that the presence of introns within ribosomal and tRNAs constitutes another fundamental difference between archaeobacteria and eubacteria.

Various disputes arose concerning archaeobacterial origins and centred on the order in which the extreme halophiles, methanogens and the extreme thermophiles separated from one another and from eubacteria and eukaryotes. The proposal by J. Lake (University of California, Los Angeles) that the sulphur-dependent thermoproteales and sulfolobales should be considered a separate kingdom because a few of their biochemical properties differ markedly from those of the extreme halophiles and methanogens received an extremely negative reaction, as did his contention (Lake, J. *et al. Proc. natn. Acad. Sci. U.S.A.* **82**, 3716; 1985) that the extreme halophiles should be grouped with eubacteria because their ribosome shapes are compara-

The loess region of China

DELEGATES from ten overseas countries recently attended the international symposium on loess research held in Xi'an, in the People's Republic of China (5–13 October, 1985), the first such meeting to be held in the classic Chinese loess region.

A 5-day field excursion before the meeting traversed several loess regions, distinguished by their geomorphological features, between Xi'an and Ansai, 400 km to the north. Our route crossed the broad Wei River flood plain which is mantled by loess and dissected by a few small gullies. Northwards, the hill country is dominated by long, loess-covered ridges termed liang. Limestone quarries along the road gave a unique opportunity to observe how the liangs are related to the underlying bedrock. Smaller, loess-covered hills, known as mao, separate this area from the flat-topped loess plateau, termed yuan. Here the loess is about 100–200 m thick and is extensively cultivated with wheat and maize, a little cotton and tobacco.

The most spectacular features of these yuans are the deep erosional gullies that dissect the plateau. In particular, near Luochuan, the gully is some 130-m deep and in the near-vertical cliffs a sequence of more than 15 palaeosols can be seen overlying the basal red clay. One site has been studied for about 30 years and the chronological sequence has been established primarily by palaeomagnetic measurements of a core nearby. These results imply that the 130-m deep section spans the last two magnetic epochs, the Brunhes and the Matuyama. Detailed magnetic stratigraphies reaching back into the Gauss normal epoch (Heller, F. & Liu, T-s *Nature* **300**, 431; 1982), indicate that loess deposition may have started as early as 2.66 Myr ago. This is similar to the 2.9 Myr date reported by G.J. Kukla (Lament-Doherty, Geological Observatory) for the beginning of

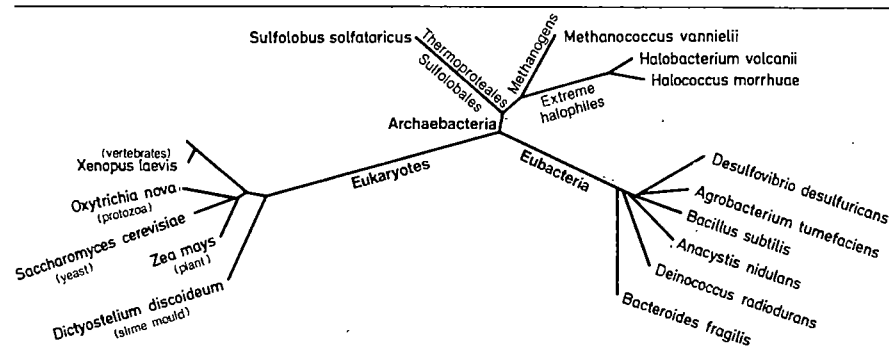

non-biogenic silica incorporation in a marine core off the Japanese coast. Similar and more continuous records are expected from the Qaidam Basin, closer to the source area of the loess, and it is tempting to correlate the palaeosols with the interglacial periods revealed by the deep-sea oxygen-isotope record.

Another feature of the symposium was the integration of geotechnical and chronological studies of loess. A large number of physical properties, such as the bulk dry-density and liquid limit, have been measured and related to the probability of landslides and collapse of loess when it is waterlogged. These properties are of interest as the area is bounded by major active faults and records document many major earthquakes in the past two thousand years.

A highlight of the field trip was a visit to an experimental conservation area, in Ansai County, Shaanxi Province, set up in 1980 by the Northwest Institute of Soil and Water Conservation of Academia Sinica. Erosion of the loess and subsequent landslides are major problems for agriculture, road maintenance and the safety of villages. Experiments designed to measure water run-off and removal of loess have been set up on the top of a hill overlooking the field station, and different types of shrubs and trees have been planted to try to stabilize the surface. We are also privileged to be the first foreigners to visit a village where the results of this research have been applied. Higher crop yields and more terracing have enabled the villagers to cover the upper slopes with trees and leguminous plants, which protect their livelihood.

Ann Wintle and Edward Derbyshire

Ann Wintle is at the Godwin Laboratory, University of Cambridge, Cambridge CB2 3RS, and Edward Derbyshire is Professor of Geography at the University of Leicester, Leicester LE1 7RH, UK.

Universal phylogenetic tree compiled from completed sequences of 16S-like RNAs. The lengths of the lines indicate sequence distances and are an approximate measure of evolutionary time. The figure was kindly provided by G. Olsen (Indiana University, Bloomington) and C. Woese (University of Illinois, Urbana).

ble and because it is unlikely that photosynthesis evolved in two separate events. In response, Woese (University of Illinois, Urbana) emphasized the importance of considering many biochemical characteristics when constructing phylogenetic trees and stressed that these problems should continue to be resolved at a molecular level. He then presented, for the first time, a universal phylogenetic tree (see the figure) based on, recently completed 16S-like RNA sequences. The lines indicate the relative sequence distances between the archaeobacteria, eubacteria and eukaryotes but the root of the tree is not defined. Although he is convinced that 16S RNA is an excellent chronometer for evolution because of its universality and slow rate of change, Woese recommends that RNA sequence data should be supplemented by pro-

tein sequences including those of the subunits of the DNA-dependent RNA polymerases and of a protein not directly associated with the genetic apparatus, such as an ATPase.

There were optimistic messages for all participants. The biotechnologists were promised heat-stable enzymes from the extreme thermophiles and genetically engineered methanogens for improving industrial processes. The molecular geneticists were offered a wealth of novel and exciting problems. And the evolutionists were shown how to refute the age-old prejudice that first there were prokaryotes and then eukaryotes, and how to infer the nature of early forms of life on Earth. □

Behavioural ecology

The limits to infanticide

from Paul H. Harvey and Anna Marie Lyles

THE true extent of infanticide among mammals is, it seems, only slowly becoming apparent. Over the years, new evolutionary explanations have been given to account for the limits to infanticide as currently perceived, but then a species crops up that breaks the rules. A new record of grisly proportions has been set by John Hoogland's observations on a wild population of black-tailed prairie dogs (*Cynomys ludovicianus*) in South Dakota¹. Offspring in more than half of the prairie-dog litters he observed are killed, usually by close kin.

Classical ethologists, such as Lorenz², argued that animals rarely kill others of their own species. Laboratory studies eventually showed that this was not true but, it was then claimed, laboratories are unnatural environments and infanticide is merely a maladaptive or pathological response to high population densities³. More recent field evidence has revealed that infanticide may be a predictable event in some natural populations. For example,

male lions (*Panthera leo*)⁴ and langurs (*Presbytis entellus*)⁵ entering a group regularly kill the young that were fathered by the males they replace.

Hrdy⁶ outlined a number of reasons why animals might kill young of their own species: the infants could represent a scarce resource, such as food (exploitation); the death of infants might increase the availability of other resources to its killer or relatives of its killer (competition); eliminating the dependent offspring of a possible future mate might increase the opportunities of mating access (sexual selection); parents might even be selected to kill particular offspring if investment in them was not likely to be worthwhile (parental manipulation); finally, some infanticide might not have adaptive significance and the eventual reproductive success of the killer could ultimately be reduced (social pathology). Competition and sexual selection account for most infanticide recorded among mammals⁷.

The main message of the most recent

News and Views article on infanticide⁸ was that, other things being equal, individuals are more likely to be selected to kill unrelated than related young, because the latter may be partially protected by kin selection. Indeed, it has been considered that, among mammals, close relatives rarely commit infanticide. In a book published last year, the editors wrote "For most mammals, however, with the exception of humans where mothers in certain circumstances may opt to abandon offspring, infants tend to be killed by unrelated individuals"⁷. Thus, although lion and langur males kill the young of their displaced rivals, thereby bringing the females back into oestrus more rapidly, the related females in a group do not kill each other's offspring, nor do males kill the young that they or their relatives are likely to have sired. Similarly, Sherman states that among Belding's ground squirrels (*Spermophilus beldingi*), "individuals never killed young of relatives (that is, cousins or closer kin)" even though "at least eight per cent of all young born were preyed on by conspecifics"⁹.

Hoogland's results¹ are a stark contrast. Out of the 73 black-tailed prairie dog litters that he observed, 51 per cent lost either some (13 per cent) or all (38 per cent) of the offspring. Most of these were killed by lactating females, 80 per cent of which were close relatives — mother, daughter, sister, aunt, niece or cousin of the victims' mothers.

Why might natural selection favour killing the offspring of a relative? Hoogland suggests that infanticidal females, which he terms 'marauders', acquire valuable food by cannibalizing the young they kill (exploitation as defined by Hrdy⁶), which helps them with the successful weaning of their own litters. In support of this idea, Hoogland shows that marauders are in better condition than non-marauders when their young are weaned, and they wean more and heavier offspring. But there are also costs: prairie dog females live in burrows alone with their young and when a lactating female is out marauding, her offspring are left undefended. Three

A prairie dog (photography courtesy of the Zoological Society of London).

females lost their own young when committing infanticide elsewhere and two more lost theirs while visiting burrows where infanticide had recently occurred. Given these costs, infanticide is most likely to pay dividends if it involves nearby burrows. The problem is that nearby burrows are usually occupied by close relatives. Prairie dogs group into coterie, consisting of female kin with an unrelated adult male. All members of the coterie defend their territory against invasion from outsiders. Attacks on distant burrows occupied by non-relatives therefore entail greater risk in both time (absence from own burrows) and danger, since a foreign coterie's defences have to be breached, as well as those of an individual burrow. Possibly, the extra benefits in genetic terms may not be worth the extra costs. □

Charles F. Richter (1900–1985)

CHARLES Richter, co-developer of the earthquake magnitude scale which bears his name, died on 30 September, 1985. He lived in California most of his life and that is where he developed his fascination with earthquakes during the embryo stages of the new science of seismology. In 1927, at Robert A. Millikan's request, he accepted a position as a physicist at the newly established Seismological Laboratory which was later to become part of the California Institute of Technology. During the 1930s he collaborated with Beno Gutenberg on a series of seminal publications entitled *On Seismic Waves* published between 1934 and 1939 in *Beiträge zur Geophysik*. These studies laid the ground work for modern observational seismology and resulted in the first detailed models of the mantle and core.

This collaboration also led to various earthquake magnitude scales and to the first complete compilation of earthquakes, published as *The Seismicity of the Earth* in 1954. Richter's book *Elementary Seismology*, which appeared in 1958, is an encyclopedia of earthquake information and is still widely used. Don Anderson

Neuroanatomy

Antibodies to acetylcholine at last

from Felix Eckenstein

IN a recent publication, M. Geffard and colleagues describe the production of antibodies to the neurotransmitter acetylcholine (ACh) and the successful use of these antibodies for the immunohistochemical localization of ACh¹. This is a remarkable breakthrough in the effort to identify cholinergic structures in the nervous system; the more so as it has been held for a long time that ACh cannot be fixed in tissue, so that the molecule cannot be localized *in situ*. Geffard *et al.* have overcome this problem by using an ingenious way to modify ACh chemically within the tissue to a form that can be fixed and localized by antibodies prepared against ACh that has been modified in a similar way *in vitro*.

Acetylcholine was one of the first neurotransmitters to be described and the vertebrate neuromuscular junction, the classical example of a cholinergic synapse, is probably the system where the physiology of synaptic transmission has been studied in most detail. But our understanding of the systems of neurones in the central nervous system that use ACh as a transmitter is much more limited. The work of Geffard *et al.* adds an important new method to those already used for the anatomical identification of neurones that use ACh as their transmitter.

Up to now, the methods for the anatomical identification of cholinergic neurones have included the histochemical localization of acetylcholinesterase (AChE), the enzyme involved in the hydrolysis of ACh^{2,3}; immunohistochemical localization of the enzyme for synthesizing ACh, choline acetyltransferase (ChAT)^{4,5}; or dry autoradiography to localize sodium-dependent high-affinity choline uptake (HACU)⁷. It has become clear, however, that AChE is also present in a variety of non-cholinergic neurones^{8,10}, which limits its usefulness as a marker. Localization of HACU is technically diffi-

cult and is also not entirely specific because non-cholinergic cells, such as rabbit photoreceptors, display HACU¹¹. So far, ChAT has been the only reliable marker for cholinergic neurones, although controversy about the specificity of antibodies to ChAT has plagued the field for a long time¹². Now that pure ChAT and monoclonal antibodies against the enzyme have become available^{4,6}, ChAT-immunohistochemistry is very useful for identification of cholinergic neurones.

In addition to confirming results obtained with antibodies to ChAT, the immunohistochemical localization of ACh offers other advantages. First, due to the limited cross-reactivity of ChAT-antibodies from different species, cholinergic neurones could be identified by this method only in vertebrates, whereas antibodies to ACh should have broader cross-reactivity. Second, the method for the preparation of antibodies to ACh described by Geffard *et al.* is simple enough for others to follow easily, whereas the preparation of antibodies to ChAT requires cumbersome purification of the enzyme.

One potential problem of the method lies in the way ACh has to be modified to allow its fixation. This step involves the substitution of the acetyl group of ACh with another group that is subsequently fixed in the tissue. It seems possible that this method will not only identify cholinergic neurones but also structures containing other choline metabolites. The rabbit photoreceptor, because of its high choline metabolism, should be a good model for testing this reservation. On the other hand, it is encouraging that the staining pattern obtained by Geffard *et al.* closely resembles that seen with ChAT-immunochemistry (see figure). This novel method is a more than welcome addition to the field, and one that is likely to add considerably to our understanding of the organization of cholinergic systems. □

Photomicrograph of ChAT immunoreactivity in 30–40 μm diameter multipolar neurones in the basal forebrain of the rat. In this area, neurones of similar morphology have been labelled by Geffard *et al.* using their antibodies to ACh.

Catastrophism is still viable

SIR—It is true, as Weissman states¹, that Innanen *et al.* proposed that the Sun's galactic motion might correlate with geophysical periods. Similar claims have been made over the years for ice ages, mass extinctions, the Earth's magnetic field reversal frequency, the extrusion of carbonates in Canada and so on. Indeed Holmes some fifty years ago, without the benefit of radiometric dating or the plate tectonic revolution, pointed out that there were 30 Myr and 250 Myr cycles in the geological record. These long-standing claims, largely neglected and only now being rediscovered, were an important element in our conception of the galactic theory of terrestrial catastrophism. But what was missing from all the papers before 1978 was a *mechanism*. And although it seems to elude Weissman, a new idea has emerged, namely that the well known periodicities in the terrestrial record may arise because of the dominating influence of giant comets on the Earth's evolution and of the molecular clouds in the Galaxy in turn on their intermittent influx (see ref. 2 for a review, including references therein). Giant comets in particular take precedence because they contain most of the incident mass: the prolonged effects of the dust input from giant comets may therefore compete with the prompt effects expected from bombardments by their larger debris.

There have been claims recently of course that the mechanism does not work on the grounds that the Sun, unlike other stars of its age, must remain so close to the galactic plane that it cannot yield any significant modulation of the comet flux^{3,4}. However, such claims neglect the fundamentally stochastic nature of the galactic interaction, affecting the Sun's orbit as well as the comet cloud. Thus the current solar orbit is anomalously flat, tending to depress the 30 Myr component, but it experiences large gravitational deflections including a probable memory-erasing disturbance during the very recent encounter with Gould's Belt⁵. Terrestrial cyclicities can only be avoided therefore if the Sun avoids molecular clouds, an eventuality that now appears to be hardly realistic.

By the same token it is misleading to favour stochasticity⁶ at the expense of cyclicity. It has been argued⁶ for example that the occurrence of large sea regressions immediately preceding the Permian and end-Cretaceous extinctions is too large a coincidence to swallow on the impact hypothesis. This comment is only applicable to the stray meteorite hypothesis⁷ however and would not apply to the galactic theory — we have ourselves pointed out that the two great mass extinctions were each preceded by the onset of a strong mixed magnetic interval. Thus the meteorite hypothesis predicts no cyclicity

ties and, like Nemesis, seems to owe its erstwhile popularity more to Californian hype⁸ than the real astronomical environment.

Whilst it seems therefore that Weissman's quixotic comment has little bearing on the status of the galactic theory of terrestrial catastrophism, the question of how the Earth responds to the huge astronomical perturbations that are now expected remains one of formidable complexity, hardly yet tackled in a quantitative fashion, and to that extent one might agree that catastrophism is as yet unexplained.

Tenuous evidence for the luminous mouthed shark

SIR—The capture of a second specimen of the 'Megamouth' shark *Megachasma pelagios*¹ has prompted further discussion of its feeding mechanism by J. Diamond in a *News and Views* article². The published description of the first specimen³ noted that the lining of the mouth had a silvery appearance with pore-like structures and reported that "At the time [24 hours after its capture] it was speculated that these might be luminescent organs, but we have no evidence for this". These initial speculations were given more prominence in an earlier popular article⁴. The account of the second specimen describes the upper jaw and palate as "remarkably iridescent"⁵ and the previous speculations have been revived and developed by Diamond, who makes a number of assumptions in support of the premise that Megamouth has a luminous mouth into which the prey (euphausiid shrimps, copepods and jellyfish) are attracted. Beguiling though such a hypothesis may be, its factual basis is too tenuous for it to be allowed to go unchallenged.

The two specimens have been captured at epipelagic depths (< 38m and 165m) yet their "eclectic combination of habitus characters"³ suggest they are relatively weak swimmers. Diamond infers from this that they live "well below the rich plankton zone" and cannot support themselves by direct filter-feeding, unlike the whale shark and basking shark. He infers further

that because the prey is itself bioluminescent it would be attracted to an illuminated mouth. There are few grounds for either inference. The nighttime biomass peak of the micronekton in general and Megamouth's euphausiid diet in particular, lies in the upper few hundred metres, rather than right at the surface. Nor is there any direct evidence to suggest that euphausiids are attracted to a bioluminescent source. There is really no basis for speculation that the mouth is bioluminescent other than its unusual iridescence. Even so, although some luminous organs are silvery it does not follow that all silvery tissues are luminous. It could equally (perhaps more plausibly?) be argued that a reflective lining to the upper part of the mouth might make it less conspicuous than a wholly dark maw, and therefore more efficient in any daytime filter-feeding.

Like Diamond, I do not know of any filter-feeder that uses light to attract plankton (although it was once suggested as a function for the luminescence of the piddock, *Pholas*⁶). The answer to the question he poses of why filter-feeders do not attract prey into their mouths is probably a function of the difficulty of generating a non-specific signal of sufficient potency and range to supply the dietary needs. It is more likely that the problem of Megamouth's feeding methods will be solved by better understanding of both its sensory abilities and its jaw and filtration mechanics. The extraordinary nasal capsules, and the suggestion that Megamouth is more closely related to the whale shark than originally suspected⁶, may both be relevant in this respect.

The analogy drawn by Diamond, between the fishy example of Megamouth's proposed pelagic moth-trap and the feathered one of the frogmouth's nocturnal fly-paper, is certainly entertaining but probably more fabulous than factual.

Scientific Correspondence

Scientific Correspondence is intended to provide a forum in which readers may raise points of a rather technical character which are not provoked by articles or letters previously published (where the Matters Arising sections remains appropriate).

Evolution as a Religion

Strange hopes and stranger fears

MARY MIDGLEY

In this controversial study Mary Midgley takes issue with a number of bizarre scientific doctrines which are often mistakenly viewed as part of Darwin's theory. While assessing the dangers inherent in such distortions the book, though not an attack on science, raises important questions about the nature of both science and religion and their relation to each other.

The Anatomy of Madness

Essays in the history of psychiatry

Volume I People and Ideas

Volume II Institutions and Society

Edited by W. F. BYNUM, ROY PORTER,
and MICHAEL SHEPHERD

The Anatomy of Madness brings together a rich and full sample of the best research conducted into the history of British and Continental European madness and psychiatry. The historical span from the Renaissance through to Freud reveals changing attitudes and policies towards madness. Fresh investigations challenge old orthodoxies, whilst a wide geographical spread offers stimulating cross-cultural comparisons.

CHINESE SCIENCE ABSTRACTS

The key to China's scientific literature

Chinese Science Abstracts is published in two parts and provides concise, informative and reliable abstracts of important articles from Chinese scientific periodicals. Articles of significant interest are selected by the Editorial Board from over 100 Chinese journals. Also included are abstracts of papers given at national and international symposia held in China. Each abstract gives full bibliographic information allowing the reader to trace and obtain the source article if required. Subject and author indexes are included in each issue.

Chinese Science Abstracts is unique - abstracts are prepared exclusively for publication in this journal and are not available from any other abstracts or retrieval system.

Part A

Published bimonthly. Each issue contains on average 450 abstracts covering:

- *Mathematics*
pure mathematics; applied mathematics;
numerical mathematics
- *Mechanics*
general mechanics; applied mechanics
- *Astronomy and Space Science*
general astronomy; solar system; stars;
galaxies and cosmology; astrometry and
astromechanics
- *Physics*
theory of physics and theoretical physics;
acoustics; optics; electromagnetism and
electrodynamics; radio physics and vacuum
electronics; semiconductors; solid-state
physics; low-temperature physics; high-
pressure and high-temperature physics;
plasma physics; heat, atomic and molecular
physics; nuclear and high-energetic physics
- *Technology*
computers; electronics; metallography;
energy; metrology

ISSN 0254-5179

Volume 1 (6 issues in 1985)

DM 520 (air); DM 495 (surface)

Part B

Published bimonthly. Each issue contains on average 600 abstracts covering:

- *Chemistry*
inorganic chemistry; organic chemistry;
nuclear chemistry; macromolecular
chemistry; analytical chemistry; physical
chemistry
- *Life Sciences*
zoology; botany; microbiology;
experimental biology; anthropology;
pedology; forestry
- *Earth Sciences*
geology; geophysics; seismology;
oceanology; meteorology; geography;
geodesy and cartography; environmental
science

ISSN 0254-4903

Volume 4 (6 issues in 1985)

DM 520 (air); DM 495 (surface)

Free sample copies available

Also available

Journal of Computational Mathematics

This journal publishes papers in English from all branches of modern computational mathematics. A special feature is the publication of articles selected by the Editors, and translated into English, from the Chinese-language journal *Mathematica Numerica Sinica*.

Listed in *Current Contents/Compu.Math.*

Volume 3 (4 issues in 1985)

Down to the roots

William Coleman

The Background of Ecology: Concept and Theory.

By Robert P. McIntosh.

Cambridge University Press: 1985. Pp.383. £30, \$39.50.

ECOLOGY began in confusion and then prospered in confusion. At the outset an interest of very different enthusiasts, ecology has retained to a singular degree a seemingly irreducible diversity of subject matter. There has been much talk of theory, and the hope that one or another proposed theoretical programme would at long last provide the foundation for effective unification of the ecologist's concerns. That happy moment has not yet arrived. Each ecologist, it appears, is fated to seek his own, often highly personal view of the science, and not infrequently history has been used as a guide in that quest.

This situation is not unique. From classical antiquity to the nineteenth century, medicine, riven by conflicting theories of disease, turned to historical narrative and analysis in order to seek doctrinal coherence for purposes of further investigation and, above all, to afford the beginning student a feeling for the principal concepts of medicine and a sense of the structure of the profession. Chemistry followed a similar course. Prior to the revolution carried out by Guyton de Morveau, Lavoisier and Dalton, from which resulted a wide-reaching theoretical framework based on the regularities of combining proportions and a transformation of chemical language, the chemist often used a historical account of chemical investigations to give shape to his discipline and to impart to newcomers a sense of its accomplishments and problems. History was thus an integral part of medicine and chemistry, not an idle ancillary activity.

It appears that Robert P. McIntosh is following a similar course. *The Background of Ecology* is divided into eight chapters, arranged thematically. All revolve about the author's main concern, the rise of "self-conscious", that is, empirically and theoretically self-aware ecology, and each tends to offer in itself a complete chronological account. This procedure entails occasional but not objectionable repetition. There is, however, another and more serious drawback to McIntosh's approach. The structure of the book dictates an episodic view of the development of ecology. The topics covered — the emergence of early ecology from natural history, dynamic/community ecology, quantification and population ecology, ecosystems and systems ecology, the awesome expectations of theoretical ecology, and ecology as popularly understood (that is, conservation and the environmental movement) — appear as if on parade,

each in multi-coloured costume and announced by contentious advertising. While McIntosh is a spectator of this parade, indeed, a very attentive and extraordinarily well-informed observer, he only occasionally views the proceedings with a sharply critical eye and even more rarely seeks to relate to his readers the meaning of the great display.

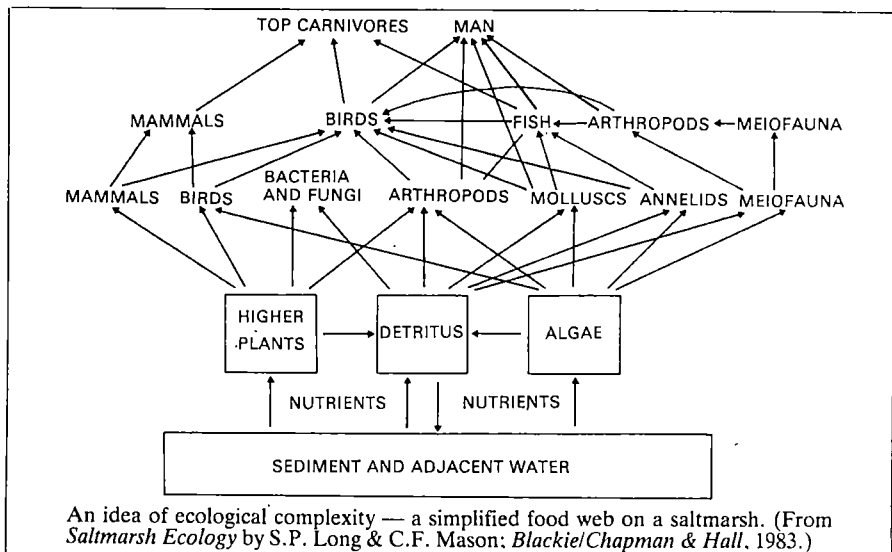

The Background of Ecology offers, in fact, a remarkable tally-sheet or taxonomy of who thought what and when, and who rose in opposition; in this lies one of its many virtues. It gives, however, little indication of why such opinions were entertained or rejected; what is largely missing from the book is a sustained analysis, an interpretation of ecology's history. Lacking this, we can conclude only that ecology has an old and respectable background and that, in more recent years, the science has pursued countless disparate objectives, all the while never being able to settle on a set of widely acceptable goals.

Of course, ecological ambitions have always been large and there is dubious merit in chiding an observer of the development of a science for not accomplishing what few of its practitioners themselves have accomplished. To early ecologists, as to their successors, it was relatively easy to state the needs of the science. Kerner von Marilaun, for example, announced in 1863 that the distribution of plants "follows immutable laws. Every plant has its place, its time, its function and its meaning". One's task followed directly therefrom: discover these laws. Nothing less would do for animals and, ultimately, for

the combined biotic world and for its relationship to the non-living world. Self-conscious ecology largely began with ambitions such as those expressed by Kerner. Botanists, exploring the spatial distribution and physiological adaptations of plants, especially the former, laid foundations for the science and created its first large-scale generalization, the notion of succession. Limnologists and marine scientists also stressed the idea of community, noting not only distinctive assemblages of organisms but emphasizing more than others the myriad interactions that bind these organisms together.

Until the 1920s, this was the primary fare of the ecologist. New possibilities then emerged. Under the protection of Raymond Pearl, and developed by Lotka, Volterra, Gause and others, the logistic curve and then two-species interactions swept animal ecology. The population now rivalled the species as the ecologist's principal interest and gradually the rich new domain of theoretical population ecology arose. Population ecologists turned to experiment and to mathematical refinement, but faced the charge that their premises represented serious oversimplification and their empirical studies ignored the complexity to be found in the field.

The 1930s announced the ecosystem concept, but that idea came into its own only after the Second World War. Joined by systems theory and enthusiastically supported by the United States Atomic Energy Commission and other agencies, ecosystem ecology became the favoured child of the post-war years. Its promise of efficiency, holistic thinking and ready applicability added to its attractions. In an unparalleled crescendo of organization and expenditure, ecosystem ecology emerged as the keystone of the International Biological Programme, ecology's debut in Big Science. McIntosh's account of these developments is both comprehensive and droll; he has a keen eye for excesses as well as for science and scientists.

One of the fundamental problems in writing the history of ecology is the fact, itself not at all unexpected, that few new trends or interpretations displaced previous views and practices. The science persists and advances in a constantly unsettled condition. There has been and remains great dispute over the basic unit or units of ecological discourse — individuals, species, populations, communities, ecosystems or still larger entities; there is disagreement over the existence, character or relative importance of various ecological generalizations — succession, biogeochemical cycling, competitive exclusion; there is now available a host of research methods, undue allegiance to any one which might, as is always the case in the sciences, commit the investigator to one interpretive strategy and exclude other, perhaps promising possibilities. As noted, McIntosh has not elected to develop his history along these thematic lines.

One should attempt to do so, however, for what is needed today, in addition to detailed chronological accounts such as that offered here, is equally detailed analysis of several questions in the history of ecology. We need to know, for example, how and why animal ecology followed a course different from that of plant ecology; why population phenomena rose to the fore during the 1920s and 1930s; what role, if any, ecology played in the evolutionary modern synthesis; what have been the advantages of large-scale scientific research; and what have been the factors behind the shifting emphasis upon cooperative and competitive ecological models. We still need, despite the flood of literature seemingly directed to the topic, a clear view of the relationship of ecology as an aspiring natural science and the environmental movement as a political, social and moral campaign. The historian's obligation is to address such matters and not to rest content with a chronicle of events.

The Background of Ecology offers excellent preparation for such study. The author omits very little in the Anglo-American tradition — Continental ecology was not part of McIntosh's brief — and provides an up-to-date and virtually exhaustive bibliography of relevant primary and secondary materials. Moreover, his classification of doctrinal tendencies and portrayal of leading controversies provides a valuable guide to a vast and still largely uncharted sea. Regrettably, only within certain of its sections is McIntosh's volume a work of incisive interpretation, but it is throughout a reference work of distinction and one which is sure to be of interest to ecologists as well as to historians. □

William Coleman is Dickson-Bascom Professor in the Humanities and Professor of History of Science and History of Medicine at the University of Wisconsin, Madison, Wisconsin 53706, USA.

Private life of radiochemistry

Alwyn M'Kay

George de Hevesy: Life and Work. By Hilde Levi. *Rhodos International, Copenhagen/Adam Hilger: 1985. Pp.147. Dkr.120, £15, \$25.*

GEORGE de Hevesy (1885–1966) was one of the great pioneers of radiochemistry, perhaps the greatest. He invented many of the principal radiotracer techniques, for which he was awarded the 1943 Nobel Prize for chemistry, and the radiochemical textbook he wrote jointly with Fritz Paneth was for years the standard work on the subject. Though a chemist, he has been called “the father of nuclear medicine”, since it was to a large extent through his efforts that this field was opened up.

There is, however, surprisingly little in print about the man himself. There are three obituaries, one based almost entirely on his autobiographical notes, but not much else. It is fortunate that his long-serving assistant has given us this book.

Hevesy emerges as an enigmatic figure. He was aristocratic, courteous, reserved; one seldom talked to him about anything but science and its affairs. He took immense pleasure in his work, which is on record for all to see, but revealed little of his inner self, even in his letters to his closest friends. Life is more than science, yet Levi has been able to record no word of Hevesy's on religion or art, hardly anything on his family, and surprisingly little on political affairs considering that Nazism forced him to move from Germany to Denmark in 1934, and then to Sweden in 1943. Having a Hungarian passport, he could make these journeys freely despite being Jewish.

The book provides some illuminating sidelights on Niels Bohr, in whose Institute Hevesy spent two long and fruitful periods (1920–1926 and 1934–1943), at Bohr's personal invitation. Bohr admired Hevesy's abilities, which were very different from his own, and eagerly encouraged him to launch into the almost uncharted area of radiobiology in the second of these periods, arranging for Levi to become his assistant. She naturally describes the resultant scientific achievements in some detail, from first-hand knowledge.

Hevesy's earlier applications of radio-tracers to physicochemical problems, starting from work under Rutherford in 1911 and 1912 in Manchester, receive less attention. So long as the only tracers available were the natural radioelements, the only quantities he could measure, such as the solubility of lead chromate, were of limited interest in themselves. There was, however, great originality in his physicochemical ideas, which laid the foundations of the tremendous later developments in the use of radiotracers.

The author's command of English is generally excellent, but in places the text would have benefited from the attentions of a sub-editor. A particular point which may mislead is the use of the phrase “first of all”, not in a temporal sense, but to mean “above all” or “primarily”. Such small blemishes apart, the book tells its story well. Scientific matters are lucidly described (though the layman may find certain passages difficult even with the aid of the glossary provided) while the biographical material will be of interest to anyone concerned with the history of physics and chemistry in the twentieth century. □

Alwyn M'Kay, Thurso, 40 Lockstile Way, Goring, Reading RG8 0AL, UK, was formerly a Group Leader at the Atomic Energy Research Establishment, Harwell. He worked with Hevesy in Copenhagen between 1935 and 1937.

Getting to grips with chaos

Michael Berry

Deterministic Chaos: An Introduction. By Heinz Georg Schuster. *Physik-Verlag*, 1985. Pp.220. DM98, \$43.75.

IN THE more fully developed sciences, natural laws are expressed as mathematical equations describing how the development of a system is uniquely related to ("determined by") its state at some other, usually earlier, time. (Quantum mechanics is no exception: its celebrated indeterminacy restricts what may be measured in any given state, not the way in which the state evolves.) Determinism does not imply predictability, however, and indeed a wide variety of systems that evolve causally, with no source of external noise, exhibit irregular and even random behaviour. The common property of deterministic chaotic systems is sensitive dependence on initial conditions: as a result of instability in the dynamical equations, two systems initially in very similar states will soon evolve to widely separated ones.

This is not a new idea. Maxwell understood it more than a century ago, and, shortly afterwards, Poincaré began to develop much of the appropriate mathematics. What is new is the emergence of "chaology" as the subject of intensive study in a variety of areas using a variety of techniques. The areas of application range from celestial mechanics (gaps in the asteroid belt) and fluid turbulence to physiological arrhythmia (heart attacks and cot deaths) and the populations in successive generations of an ecosystem. The techniques range from physical experimentation through computer simulation to the purest mathematics.

In his book, Schuster gives a very useful summary of the main ideas of the subject as it now stands. Although a physicist by training and style, he organizes his treatment by the logic of the mathematics, which is based on the concept of a dynamical system. This is any set of equations, describing how a set of variables changes with time, for which a uniqueness theorem guarantees that for each specification of the variables at one time (initial state) there is just one set of values at a later time (final state). This is a very broad framework: "time" may be continuous (as in mechanics, classical or quantum) or

discrete (as in the successive generations of an ecosystem); the set of variables may be finite (like the coordinates and velocities of a finite collection of particles) or infinite (like the triplet of velocity components at each position in a fluid).

Most of the book is devoted to simple mappings, where dynamics is reduced to a rule describing how a point in a low-dimensional space (a plane or even a line segment) jumps from "time" n to "time" $n+1$. This is a sensible strategy because much more complicated systems (such as turbulent fluids) appear to have, embedded in them, mappings which organize much of their behaviour. And astonishing complexity can indeed arise from multiple repetition of a simple map. Unraveling this has led to new concepts of wide applicability — strange attractors, Feigenbaum sequences, Lyapunov exponents, Kolmogorov entropy, for example. These and more are explained with maximum

clarity and the minimum (but subtle) mathematics; abundant illustrations, including beautiful colour plates, also help the reader along.

When there is no friction (a useful idealization in celestial mechanics and particle accelerators) different concepts apply. These are well summarized but, as the author admits, his treatment here is less original because many other accounts of this topic are available. Finally, the question of chaotic behaviour in quantum systems is discussed, with the caution appropriate to the unsettled state of the subject.

Students about to begin research into chaos, and practising scientists new to the subject, will find this a book well worth reading. □

Olfactory work

D. Michael Stoddart

Social Odours in Mammals, Vols 1 and 2. Edited by Richard E. Brown and David W. Macdonald. *Clarendon*, 1985. Pp.882. Vol. 1 £45, \$60; Vol. 2 £32, \$45.

It is difficult to know whether this work is a review or a textbook — it has some of the characteristics of both. The editors say they were prompted to gather together contributions from their band of 13 authors because

the growth of theoretically exciting ideas concerning social odours, the scattered publications and expertise [gave us] the feeling that a systematic review of the whole class could provide a realistic perspective and a useful reference work.

Perhaps if they had clarified their objectives rather more they would have decided on what exactly they wanted. In my opinion *Social Odours in Mammals* is, if anything, a textbook cum reference work, although very different styles are adopted by each author. Its lack of success as a review rests largely on the poor coverage of the literature published during the current decade. Scanning the 20 bibliographies to be found at the end of each chapter one sees very few references post-1981, and most of the 1983 and 1984 references (I found only one of the latter) are to papers written by the chapter authors themselves. Book production is a notoriously slow business, but the price for delay has here been high. Olfactory biology is a rapidly developing field in which an effective review must be up to date.

The textbook quality stems from the books' rigorous taxonomic approach to the essentially functional set of phenomena referred to in the title. It is a great pity

there is no subject index (the four indexes included — author, common names, Linnean names and odour sources — occupy almost 50 pages), for there is no way, other than by reading the whole work, to find the latest ideas on, say, scent marking, or species or individual recognition. And no quick way of discovering if advances in specific areas of rodent olfactory biology, to which much space is devoted, are paralleled in other groups. This is an omission which substantially mars the books' usefulness.

What these two volumes do provide is a series of articles examining all that is known about the role of odours in mammals. The rodents are dealt with in four separate chapters — one on the effects of odour on reproductive physiology, one on the *Myomorpha*, one of the *Sciuromorpha* and one on the *Hystrichimorpha*. The primitive eutherians and the primates are given a different treatment: a whole chapter is devoted to a case study of the tree shrew, for example, and a chapter each to the saddle-back tamarin and to human beings. Special treatment for these and not for other well-worked species, such as the golden hamster and the Norway rat, seems inconsistent. Nonetheless, the case-histories provide excellent overviews of the work of two or three leading laboratories in the field. I also particularly enjoyed the chapters on marine mammals and the edentates and pholidotes, as these groups are seldom covered. In all chapters the treatment is thorough, and many tables enhance the presentation.

As an initiate in the field of olfactory biology I find this a useful, if somewhat eclectic, reference work. But I will direct my students to other works to gain a more rounded and up to date impression of the subject. □

The classic anatomist's textbook *The Development of the Vertebrate Skull* by Gavin R. deBeer — first published in 1937 — has just been reprinted with a new Foreword written by Brian K. Hall and James Hanken. The book is published by the University of Chicago Press. £18.95, \$22.

Build-up around the planet

John Noble Wilford

The Space Station: An Idea Whose Time Has Come. Edited by Theodore R. Simpson. *Institute of Electrical and Electronics Engineers, New York/STM Distribution, Enterprise House, Ashford Road, Ashford, Middlesex TW15 1XB, UK:1985. Pp.295. \$19.95, £18.*

COMING to terms with the proposed American space station in any rational way is little short of impossible, if only because of what it is not. Unlike the Apollo Project, it is not a programme with a specific destination (the Moon) or a clear political objective (a bold challenge to Soviet leadership in space). Unlike the Space shuttle, it lacks the coherence of a single piece of hardware already agreed on and with a single function, which was to make travel to space more routine and perhaps less expensive. (No matter that this latter objective has yet to be realized; it was the project's decisive selling point.) What, then, can be said of or for the space station?

In directing the National Aeronautics and Space Administration (NASA) "to develop a permanently manned space station, and do it within a decade", President Reagan in 1984 offered few details of the station's architecture, capability or purpose. He spoke only of following "our dreams to distant stars, living and working in space for peaceful, economic and scientific gain". And even though NASA had lobbied fervently for the project, its officials had no specific engineering plans ready for carrying out the Presidential order. One of their first acts was to issue contracts to industry to develop space station designs and to identify who might need or want to use such a facility. Nearly two years after President Reagan's speech, the idea has yet to be translated into firm plans.

This much can be said: the space station is supposed to be a large facility in a near-equatorial Earth orbit, about 300 km above the surface. It would be composed of several units, including a control centre and a module for housing crews or as many as ten people. These components would be launched separately from the Space Shuttle. The facility would grow module by module to meet demand for laboratories for microgravity research, materials-processing "factories", remote-sensing platforms and staging bases for missions to more distant orbits and the planets.

Some of the visions and engineering particulars for such a facility are described in *The Space Station*, which is a collection of articles by NASA officials, politicians,

science policy makers and engineers. Although the prevailing view is favourable to the principle of the space-station, the book cannot be dismissed as a propaganda tract. The editor, Theodore R. Simpson, an experienced aerospace engineer, has included several valuable discussions about the history and process of American decision-making in space matters. Several of the contributors are sceptical of the idea.

For those who want a preview of what the orbiting facility might be, two NASA engineers offer a comprehensive discussion of various designs that have been considered. In the book's illustrations, the station is usually characterized as a cluster of cylindrical modules, docking ports for shuttles and the long arms of solar-power panels. Romantics will be disappointed, for nothing resembles the toroidal station in the movie *2001: A Space Odyssey*. But as other contributors, from the Congressional Office of Technology Assessment, point out, "We would be surprised if NASA's present space station plans were carried through to completion without major change". They suggest that, in the absence of clear-cut goals, "it is simply not yet possible to judge, objectively, whether or not NASA's presently suggested infrastructure elements are truly appropriate and worth their substantial cost".

Similar reservations are expressed throughout the book. The Pentagon's lack of enthusiasm, reiterated in one chapter, must be of particular concern to space station advocates; Pentagon backing is usually essential to big-money space efforts.

Thomas M. Donahue, a physicist at the University of Michigan, who heads the Space Science Board of the National Academy of Sciences, states the opposi-

tion of many scientists to the idea. They doubt that a space station would add significantly to what they can already accomplish with the shuttle and automated satellites. Moreover, they fear that the station's costs will drain money from their own cherished projects. But Dr Donahue seems resigned to the station's inevitability: "We hold that the decision to build a space station will be made for reasons other than its usefulness to space science and applications".

Victor M. Reis, a former science policy adviser in the Reagan Administration, takes this point even further. He acknowledges that each and every one of the projected space station missions could be done well by a judicious combination of shuttles, Spacelabs, automated platforms and satellites. Nonetheless, he argues that there is one "powerful argument" in support of the project, which is, in effect, to assure NASA of a robust future. Mr Reis is probably correct in calling this "the fundamental issue" of the space station decision. But he cautions that a decision to go forward with the project would be justified only if "it can be done in harmony with NASA's other missions and responsibilities". This will not be easy, he notes, because NASA's big manned programmes have a way of consuming the lion's share of NASA's budgets.

The Space Station will not be satisfying to those who seek to win converts to the space-station cause or to those who are its outright opponents. More than most of the authors may have intended, the book reveals why the project has so far had such a cool to mixed reception. □

Not yet a reality — the concept of a Space Operations Center developed by NASA in 1979.

Sociological problems of high-energy physics

from Andrew R. Pickering and W. Peter Trower

Large-scale collaborative projects between experimental high-energy physicists have produced sociological problems that will need thought to resolve.

TEAM research entered the study of elementary particles in the immediate aftermath of the Second World War. The collaborative methods which had borne fruit in the Manhattan Project were carried over into the new speciality of high-energy physics. The most visible early manifestation of this organizational transfer was at the Radiation Laboratory of the University of California, Berkeley, where E.O. Lawrence's pre-war development of the cyclotron had led to a central role in atomic weapons research¹. As R.R. Wilson, the first director of the Fermi National Accelerator Laboratory, recalled in 1970, "A word was even coined — Berkeleitis — to describe the syndrome that existed there"².

Despite the misgivings of physicists who harked back to the pre-war days of individualistic research, Berkeleitis soon became endemic to high-energy physics, growing more rampant with the passing years³. Until the mid-1960s it was still possible for a small group of, say, less than ten physicists to make a significant contribution to high-energy physics; by the late 1970s the complement of a typical collaboration had grown to around 50. Today, groups of around 200 physicists are assembling in preparation for experiments at Europe's next new big machine — the Large Electron-Positron Collider (LEP), due to come into operation at CERN, Geneva, in 1987.

As collaboration size has grown, so too has the duration of typical experiments. In the 1960s an experiment could be mounted and data analysed within a period of months, while current experiments can span more than a decade from first conception to final publication of results. Thus, in terms of both personnel and duration, high-energy physics experiments have moved ever further from the pre-war stereotype of the lone researcher at the laboratory bench, and have come more to resemble large-scale engineering projects.

Trends

The underlying trend towards larger collaborations and extended timescales in experimental high-energy physics is not hard to understand. The relatively generous funding which high-energy physics has enjoyed throughout its history has made possible the construction of a succession of particle accelerators of ever-increasing size, and sophisticated experimental techniques have been developed to exploit the

high-energy beams thus made available. Instead of a single detector, a modern experiment deploys a complex multi-element array, costing millions of dollars and requiring an army of specialists to design, build and run. Considerable resources are also required for subsequent data analysis.

Neither is it hard to appreciate the benefits of this form of research. The discoveries at CERN of the electroweak intermediate vector bosons, W^\pm and Z^0 , made by two groups totalling nearly 200 physicists, were the culmination of a decade of rapid progress in understanding elementary-particle interactions. But such benefits have been bought at a price. Our aim here is to outline the sociological problems which are the symptoms of Berkeleitis. Our discussion is organized around twin themes: the frustration of individual initiative and creativity within large collaborations, and the consequent tendency to conservatism and orthodoxy in communal practice. (The frustrations inherent in team research have been impressed upon us in informal communication with many experimenters. It seems clear that the present trend towards non-accelerator experiments (for example, searches for free quarks, magnetic monopoles, proton-decay) is, in part, a manifestation of these frustrations.) We will show that the problems arising within individual experiments spill over into programmes of experiment. They are reinforced by the institutional structure of experimental high-energy physics, and have been further exacerbated by conceptual developments in the field over the past decade. Finally, we ask whether anything can be done to check current trends to gigantism and orthodoxy in high-energy physics research.

The rationale for team research is the division of labour. A large collaboration comprises several groups of physicists, each drawn from a single university or laboratory. In setting up and running an experiment, each group takes on responsibility for particular elements of the overall apparatus. Data analysis is likewise broken down into component tasks allotted to different groups. Thus, along with the division of labour goes a degree of specialization beyond that normally associated with scientific research.

This is where sociological problems begin to arise, particularly for junior physicists — postgraduate students and young postdoctoral researchers. Even within a

single group of experimenters, research tasks are subdivided. And junior physicists are usually those responsible for the basic items of hardware and software. They thus acquire detailed knowledge of only one small part of an enormous and diversified project, and their chances of making a significant contribution to the overall course of the experiment outside their area of expertise are slight.

Managers

Senior physicists encounter a similar problem, but for different reasons. They oversee and coordinate the work of a group or groups, and are thus obliged to take on administrative responsibilities more familiar to managers of large technological enterprises. Another function of senior physicists is to secure the material resources necessary for the success of the experiment, and to negotiate with laboratory managements for beam-time, workspace and so on. Here they function as entrepreneurs. Again, even at the most senior level, the role of creative scientist can be submerged for long periods of time (if not forever) by the multifaceted organizational demands of a large collaboration.

In a variety of ways, then, many physicists find their creative ambitions and aspirations frustrated in the course of high-energy physics experiments. And, all things being equal, opportunities for innovation decrease in proportion to the degree of specialization and the associated administrative load — that is, in proportion to collaboration size and the duration of the experiment.

Only in a field where long experiments were commonplace, though, would one even look for creative opportunities within the development of a single experiment. The classic locus for creativity in experimental science lies in the gaps between experiments: in the conception of new techniques or new problems to tackle. But here too Berkeleitis has a deadening effect. One can discern at least two sources of conservatism in experimental design in high-energy physics. The first is that specialization is self-reproducing. As discussed above, in his research training, the young physicist acquires a narrow, specialized competence in some limited aspect of experimental high-energy physics. This competence then becomes his most precious asset in the pursuit of a research career, so valuable (to himself and to others) that opportunities for future variety in research practice are highly

circumscribed. And the upshot of this is an inhibition of technical innovation within high-energy physics experiment as a whole.

Since techniques are usually appropriate to the exploration of a limited class of phenomena, technological conservatism itself implies conservatism in the choice of research problems, and both forms of conservatism are reinforced by a second source: the fear of failure. The senior physicist, or physicists, who propose to conduct a contemporary high-energy physics experiment risk not only their personal reputations, but also the efforts and careers of the many less senior physicists who will be involved in the project. If the experiment fails — if it does not produce interesting data or, indeed, any data at all — hundreds, possibly thousands, of man-years of effort and millions of dollars will have been wasted. Not surprisingly, therefore, there is a tendency to conservatism in experimental programmes, with new experiments aiming to investigate phenomena of well-established interest using well-established techniques.

Rewards

So far we have outlined the obstacles to initiative and creativity implicit in collaborative research of long duration: the twin requirements of specialization (with its self-reproducing character) and administration, and the ever-present risk of failure. In themselves, the impact of these factors can be overestimated. Against them must be set the potential rewards for successful innovation — symbolic rewards like Nobel prizes, and material rewards such as career advancement. There are, however, institutional factors in high-energy physics which serve to structure even successful innovations, to foster a limited set of technological developments or problem choices at the expense of others. This, too, is a form of conservatism, which again acts to stifle individual initiative.

The origins of institutional conservatism in high-energy physics lie in the centralization of research resources. Despite generous funding, the expense of building and running particle accelerators has long been beyond the resources available to individual universities. Over the history of the field, the facilities for high-energy physics experiments have been gathered together into a handful of regional, national and international laboratories at which collaborations assemble to perform their experiments before departing to their home universities for data analysis.

Together with the centralization of research resources has gone a proliferation of committees. Access to experimental beams and funding for experiments are controlled by committee, likewise planning and funding for new facilities — new accelerators or new major items of experimental equipment. Thus any potential innovator is faced with an institutional

hurdle. The typical disposition of committees towards conservatism is well known, and the experimenter who does not propose to tackle an established problem with established techniques is likely to find his proposal rejected.

As Nobel Laureate Luis Alvarez put it: "Our present scheduling procedures almost guarantee that nothing unexpected can be found". As it happens, there is a twofold irony to this quotation. In his leadership of the 72-inch bubble chamber programme at Lawrence's Radiation Laboratory, Alvarez did more than any other to demonstrate the benefits of Berkeleyitis in experimental high-energy physics⁵. (For a discussion of the Alvarez group, see ref. 6.) And at the time when he wrote, 1973, high-energy physics was characterized by a pluralism of research strategies that was soon to vanish.

The 1970s saw the rapid development of the 'new physics' world-view in high-energy physics, in which the world was seen to be built from quarks and leptons interacting according to the dictates of twin gauge theories — quantum chromodynamics (for the strong interaction) and the Weinberg–Salam–Glashow unified electroweak theory. And the sociological correlate of the 'new physics' was the 'new orthodoxy' (as it was christened by high-energy physics theorist James Bjorken)⁷. Within the new orthodoxy, communal research practice in high-energy physics became almost exclusively organized around the new-physics world-view. The effect was most striking in the experimental fields, where the institutional committee structure reflected the majority view and effectively enforced the new-physics dominance of research. Since the late 1970s it has been difficult, if not impossible, to mount a high-energy physics experiment which does not promise to engage directly with the interests of gauge theorists.

One consequence, then, of the rise of the new orthodoxy has been a close circumscription of opportunities for initiative in the choice of topics for experimental investigation. Along with this restriction on problem choice have gone restrictions on acceptable forms of technical innovation. As currently elaborated, gauge theory offers an analysis of only a limited range of rare phenomena. Investigation of those phenomena (in the presence of an overwhelming background of 'uninteresting' processes) requires large, complex experiments and highly sophisticated electronics — precisely the experiments which call for large collaborations working together over a period of years. Larger and larger teams have assembled to man the ever-larger experiments expected to probe the fine details of already rare phenomena, leading to the projection of 200 member teams for LEP.

Thus, more than any other factor, it has been the new physics (via the new orthodoxy and the institutional structure of

high-energy physics) which has driven the trend to gigantism in experimental physics throughout the 1970s and into the 1980s. And, as an unintended consequence, it has multiplied all of the sociological problems discussed above. The degree of specialization in the experimental physics community, the extent of administrative responsibilities and the risks attached to failure have all increased with the coming of the new physics. Opportunities for initiative and creativity have decreased in proportion.

The new physics, then, through the grip of the new orthodoxy on experimental high-energy physics, is experienced by many physicists as making the life of the researcher more frustrating and less rewarding. What of the future? At present, the new orthodoxy, with its attendant drive to gigantism and the multiplication of sociological problems, is set to reproduce itself indefinitely. Through the institutional structure of high-energy physics, the future as well as the present of experimental research has been given over to the new physics. The next generation of big machines — at which the next generation of experimenters will learn their trade — are explicitly conceived as new-physics facilities. LEP, for example, is intended to operate as an intermediate vector boson factory (see, for example, ref. 8).

The state of high-energy physics is therefore not entirely satisfactory, despite the conceptual triumphs of the new physics. The existence of a self-perpetuating orthodoxy is anathema to many physicists, especially an orthodoxy which multiplies pre-existing sociological problems by further stifling opportunities for individual initiative. The question arises: can anything be done to ameliorate this situation? Clearly, a return to the pre-war days of the lone researcher is impossible — Berkeleyitis is intrinsic to the technical and institutional fabric of experimental high-energy physics — but can the slide into gigantism be checked (for those who wish it)?

Here there is a straightforward suggestion. The institutions of high-energy physics should be used to relax rather than to enforce the stranglehold of the new physics upon experiment. A fraction of the available resources should be set aside for those who would, for one reason or another, follow a heterodox path. In this way, the oppressive aspect of the current orthodoxy could be *de facto* eradicated. And, since it is the new-physics emphasis on rare phenomena which is driving the present increase in collaboration size and experiment duration, the route would be open for individualistically inclined researchers to move towards their chosen form of practice. Unconventional paths of inquiry could be followed, novel small-scale experimental techniques could be developed and old techniques rescued from oblivion, all with unpredictable but possibly major consequences for future

patterns of research.

It is important to stress that the argument is not that the new-physics world-view should be abandoned — its virtues are too well established for that — but simply that some opportunities should be left for research outside the orthodoxy. (It is worth recalling that it was precisely such heterodox research that led to the 1974 discovery of the J-psi particle and the establishment of charm — an episode that marked a watershed in the development of the new physics.) Of course, in comparison with a well-established orthodoxy, heterodox experimental proposals inevitably appear lightweight — perhaps frivolous or even incomprehensible — and committees find it correspondingly hard to support them. But this point has already been adequately dealt with by the mathematical physicist Freeman Dyson, who suggests that funding agencies should allot somewhere in the region of 10–25 per cent of their resources to heterodox research. (The figure of 10 per cent is also suggested by Muller. Alvarez argues that proposals in experimental high-energy

physics should be assessed solely on the basis of the experimenters' past performance, and without regard to consensually perceived theoretical significance.)⁹

It should be noted that although this article has focused upon sociological problems arising in experimental high-energy physics, problems also exist in theory. Here again institutional structures presently act to discourage practice outside the gauge-theory orthodoxy. Dyson's article is, in fact, concerned with encouraging theoretical rather than experimental diversity. His conclusion is, however, relevant to both theoretical and experimental practice: "We should not be afraid of looking foolish or even crazy. We should not be afraid of supporting risky ventures which may fail totally . . . Organizations which only support research where there is no chance of mistakes will in the end support only mediocrity. If we proceed with good sense and courage to support unfashionable people doing things that orthodox opinion considers irrelevant or crazy, there is a good chance that we shall rescue for science . . . people

whose ideas will still be famous long after all our contemporary fashionable excitements are forgotten".

Concentration of methane in the troposphere deduced from 1951 infrared solar spectra

Curtis P. Rinsland, Joel S. Levine & Thomas Miles

Atmospheric Sciences Division, NASA Langley Research Center, Hampton, Virginia 23665, USA

The 1–2% increase in tropospheric methane determined from gas chromatographic measurements since 1977 has important implications for atmospheric photochemistry and climate. To extend the measurement baseline, we have analysed solar absorption spectra and determined mean troposphere CH₄ mixing ratios for the years 1951 and 1981, and find an average rate of CH₄ increase of 1.1 ± 0.2% per year for this period.

ALTHOUGH methane is only a trace atmospheric constituent at the part per million by volume (p.p.m.v.) level, it has a significant impact on the photochemistry of both the troposphere and stratosphere and on the Earth's climate. In the troposphere, the methane oxidation chain initiated by the reaction of CH₄ with the hydroxyl radical (OH) leads to significant photochemical production of H₂, CO and O₃ (ref. 1). In the stratosphere, CH₄ is a source of odd hydrogen species (HO_x) which catalytically destroy O₃ (ref. 2). In addition, CH₄ reacts with atomic chlorine in the stratosphere, terminating the odd chlorine cycle, which catalytically destroys O₃ (ref. 2). Methane also contributes to the atmospheric greenhouse effect by its absorption in the 7–14-μm spectral region³.

Over the past 5 years, several studies have reported that levels of CH₄ in the troposphere may be increasing. The analysis of urban or suburban total hydrocarbon data in New Jersey over 10 years (1968–1977) led to the suggestion that CH₄ (which was not monitored explicitly, but is the major component of the measured total hydrocarbon concentration) may have increased at the rate of ~0.6% yr⁻¹ (ref. 4). Analysis of almost 1,600 nearly continuous measurements of CH₄ obtained over a 22-month period (January 1979–October 1980) at Cape Meares, Oregon, indicated that CH₄ was increasing at a rate of 1.9 ± 0.5% yr⁻¹ (ref. 5). A similar increase was found in measurements over

western Europe from 1977 to 1981 (ref. 6). Measurements of CH₄ between November 1977 and November 1980 in remote locations between 55° N and 53° S indicate a 1% yr⁻¹ increase in CH₄ between January 1978 and January 1980 (ref. 7). Additional Cape Meares measurements obtained between October 1980 and December 1981, as well as 3 yr of measurements from the Arctic Circle to the South Pole, suggest a global increase of 1–1.9% yr⁻¹ (ref. 8). The results of >800 CH₄ measurements over southern Australia (September 1980–March 1983), from the surface to the upper troposphere, show an average rate of tropospheric CH₄ increase of 1.3% yr⁻¹ at December 1981 (ref. 9). Three different sets of CH₄ measurements were examined for trends by Ehhalt *et al.*¹⁰: (1) 49 tropospheric profiles obtained from 1965 to 1967 and 1971 to 1974 by aircraft flights at the National Center for Atmospheric Research (NCAR); (2) measurements obtained from 1968 to 1979 from ships and aircraft by the Naval Research Laboratory (NRL); and (3) published measurements of the total atmospheric CH₄ column amount deduced from ground-based infrared spectra recorded between 1948 and 1975. Ehhalt *et al.*¹⁰ summarized their conclusions from these three data sets, as well as the other measurements of CH₄, in the following way: (1) There was little or no increase in CH₄ between 1948 and 1965, shown by published analyses of the ground-based infrared spectra. (2) NCAR

and NRL measurements and the data of Graedel and McRae⁴ indicate a $0.5\% \text{ yr}^{-1}$ increase in CH_4 between 1965 and 1975. (3) There is good evidence for a global CH_4 increase of $\sim 1\text{--}2\% \text{ yr}^{-1}$ between 1978 and 1980 based on several sets of measurements⁵⁻⁸.

Ehhalt *et al.*¹⁰ also discuss the analyses of air trapped in Greenland and Antarctic ice from 100 to 2,500 yr ago, which yield significantly lower levels of CH_4 (refs 11-13). Ehhalt *et al.*¹⁰ suggest that these low CH_4 levels are caused either by lower levels of atmospheric CH_4 at the time the air was trapped in the ice or by trapped CH_4 that may have been lost by diffusion through the ice. They conclude that the relation of CH_4 levels in ice to the atmospheric CH_4 levels of the past remains unclear.

Although the published ground-based infrared spectral measurements indicate little or no increase in CH_4 in the troposphere between 1948 and 1965 (ref. 10), these early studies were limited in their accuracies by uncertainties in the assumed values for the spectroscopic line parameters, the vertical CH_4 profile shape, the vertical pressure-temperature profile and the relatively simple methods of analysis available at that time. To obtain a more accurate determination of the early CH_4 tropospheric concentration, we initiated a study to deduce the levels of tropospheric CH_4 and other gases from such historical spectra.

Here we report an analysis of infrared solar absorption spectra recorded in April 1951 at the Sphinx observatory of the Jungfraujoch International Scientific Station in the Swiss Alps (latitude 46.5° N , longitude 8.0° E ; elevation 3,578 m)¹⁴. We have used the best available line parameters for CH_4 and interfering lines of H_2O in the analysis, and determined the average tropospheric mixing ratio of CH_4 from a line-by-line, multi-layered atmospheric, nonlinear least-squares spectral fitting procedure. Correlative radiosonde and surface pressure-temperature measurements were used to determine the vertical pressure-temperature profile for the analysis. A mean tropospheric mixing ratio of $1.14 \pm 0.08 \text{ p.p.m.v.}$ has been deduced for CH_4 from the analysis. As uncertainties in line parameters remain a problem in interpreting spectroscopic data, we also derived the mean concentration of CH_4 in the troposphere from analysis of the same region in Kitt Peak solar spectra taken in February 1981. From the derived value of $1.58 \pm 0.09 \text{ p.p.m.v.}$, which is close to other modern determinations, and our value for April 1951, we determine an average rate of increase of $1.1 \pm 0.2\% \text{ yr}^{-1}$ for 1951-81.

Detailed spectral analysis is the key to deducing the concentrations of trace species in the troposphere from historic solar spectra. Hence, most of this paper deals with the spectral analysis that led to the determination of a significantly lower tropospheric concentration of CH_4 in 1951, and with the reconciliation of this new, lower value with the older, higher spectral-deduced values.

Observations and spectral analysis

The Jungfraujoch measurements selected for analysis were made with a coelostat and Pfund-type prism-grating spectrograph on the morning of 15 April 1951, between 09 h 59 min and 10 h 17 min UT. These data cover the $2,901\text{--}2,926\text{-cm}^{-1}$ spectral interval and have been published as part of an infrared photometric atlas¹⁴. According to Table 2 of the atlas, the zenith angle during the measurements decreased from 41.5 to 39.8° . The infrared signal was detected by a Perkin-Elmer thermocouple together with a 13 c.p.s. chopping system and amplifier manufactured by the same firm and connected to a Leeds and Northrup type-G Speedomax recorder. A grating with a $16 \times 12 \text{ cm}$ ruled surface and an effective slit width of 0.24 cm^{-1} was used in the region considered here. Additional details of the instrumentation are given in the atlas¹⁴ and elsewhere^{15,16}.

Absorption in the analysis interval is dominated by lines of CH_4 with minor contributions from water vapour and solar lines. The spectral data were digitized from the atlas using a Houston Instruments Hipad digitizer attached to a model PGM-2 computer (Superset). The zero-signal level indicated in the atlas has been assumed. The wavenumber scale of the digitized data has been calibrated based on measurements of the line centre posi-

Table 1 Some atmospheric parameters assumed in the analysis of Jungfraujoch spectra

Layer boundaries (km)	Temperature (K)	Pressure (mbar)	CH ₄ mixing ratio (p.p.m.v.)	
			Case A	Case B

Total vertical column amount of air molecules $1.380 \times 10^{25} \text{ cm}^{-2}$. Altitude of the tropopause $\approx 10.2 \text{ km}$.

tions of 13 absorption features distributed nearly evenly in wavenumber throughout the region. The centre positions were obtained with a line-finding algorithm similar to that used in a recent analysis of CO_2 laboratory spectra¹⁷. For unblended lines, the wavenumbers from the 1982 Air Force Geophysics Laboratory (AFGL) major gas compilations¹⁸ were adopted. For blended features, a strength-weighted mean position from the 1982 AFGL major gas compilation¹⁸ was adopted initially; this value was refined by measuring the line centre position of the feature in a preliminary least-squares best-fit calculated spectrum. Linear interpolation was used to determine the wavenumbers of data between the calibration points.

Three sources of meteorological information were used in the determination of the profile of pressure and temperature as a function of altitude above the Jungfraujoch station on 15 April 1951: (1) surface measurements of pressure (P) and temperature (T) at the Jungfraujoch station on 15 April, interpolated for the time the infrared spectrum was recorded (P. Hachler, personal communication); (2) tropospheric radiosonde P - T soundings from Payerne (46.5° N , 6.6° E) for 05 h UT on 14 April and 16 April (P. Hachler, personal communication); and (3) stratospheric-mesospheric climatological P - T profiles for April derived from a composite of 5-20 yr of daily radiosonde and satellite measurements for the mid-latitude Northern Hemisphere^{19,20}. The above information was used to define the P - T profile up to the upper mesosphere; above this altitude, mid-latitude standard atmosphere values for spring were assumed²¹.

The tropospheric portion of the P - T profile was derived by first interpolating the two Payerne radiosonde profiles to the time and date of the spectroscopic measurements. Not surprisingly, the interpolated values corresponding to the altitude of the Jungfraujoch station (650.5 mbar and -12° C) differed slightly from the surface measurements (655 mbar and -14° C). To improve the compatibility of these two sources of meteorological information, we adopted the measured surface values and adjusted slightly the altitudes corresponding to the interpolated upper air P - T measurements, using the hydrostatic equation. A standard meteorological thermodynamic diagram was used for this purpose.

The 17-layer model adopted in the analysis of the Jungfraujoch spectrum is presented in Table 1. The airmass per layer was calculated with the FSCATM ray-tracing program from FASCOD1C²², assuming the P - T profile discussed above and the mean solar zenith angle given for the observations¹⁴. The pressures and temperatures listed for each layer are effective values weighted by the density of air along the refracted atmospheric path.

Ground-based solar absorption spectra contain only very limited information about the altitude distribution of atmospheric gases. Therefore, we have assumed a relative mixing-ratio profile for both CH_4 and H_2O based on reported measurements. The absolute values are derived by scaling the relative mixing ratio in each layer by a single multiplicative factor determined for each gas from the spectroscopic analysis.

As no measurements of the vertical distribution of CH_4 were made in 1951, calculations have been performed assuming two profile shapes based on recent data (Table 1). For both cases, we have adopted a constant mixing ratio of 1.60 p.p.m.v. below 12 km. The stratospheric portion of the case A profile is representative of CH_4 measurements made between 40°N and 60°N using *in situ* and remote techniques, including the results of the NIMBUS 7 Stratospheric and Mesospheric Sounder (SAMS) instrument. It has been obtained by drawing a smooth curve through the values presented in Fig. 7 of ref. 23. The case B profile assumes higher mixing ratios in the upper stratosphere than were usually observed by NIMBUS 7 SAMS at 40°N – 60°N . It is representative of results from the same data sources for the 20°N – 40°N latitude range and has been derived in the same way from Fig. 6 of ref. 23. The case B values have also been used in the analysis of the 1981 solar spectra from Kitt Peak (32°N). The 1962 US Standard Atmosphere water vapour distribution²⁴ has been adopted for the H_2O profile shape. High-resolution ground-based spectra show lines of NO_2 in this spectral region^{25,26}. Although these lines are too weak to be identified in the Jungfraujoch spectra, we have included them in the radiative calculations assuming a published NO_2 reference profile²⁷.

Line parameters for CH_4 , H_2O and NO_2 were taken from the 1982 AFGL major and trace gas compilations^{18,28}. A T^{-n} temperature dependence was assumed for the air-broadened half-widths with values of $n=0.9$ for CH_4 , $n=0.5$ for H_2O and $n=0.92$ for NO_2 . The value for CH_4 is based on several sets of laboratory measurements^{29–31} that have found values of n near unity for self-, N_2 - and air-broadening. The value for NO_2 is taken from a recent study on the N_2 broadening of lines in the ν_3 and $\nu_2 + \nu_3 - \nu_2$ bands³². The value of $n=0.5$ for H_2O corresponds to the assumption of a temperature-independent collision diameter.

The analysis using the technique of nonlinear least-squares spectral curve fitting follows the procedures described recently for the interpretation of high-resolution ground-based spectra^{33,34}. This method has proven particularly suitable for the present study because of its accuracy in establishing the background level and its usefulness in regions of overlapping absorption lines, as observed in the Jungfraujoch data. In this study, a total of four parameters were adjusted simultaneously in the least-squares fittings to the digitized spectrum (point spacing = 0.02 cm^{-1}). Two of the parameters model the instrument response: one is for the background level of the spectrum and the other is used to fit the instrument line-shape function. Gaussian slit functions have been found for two representative grating spectrometers³⁵. We assumed this line shape in our analysis with the width of the gaussian function as an adjustable parameter in the least-squares fits. The other two parameters are the multiplicative scaling factors that convert the relative profiles of CH_4 and H_2O to absolute values.

Two sections of the digitized Jungfraujoch data were analysed assuming the case A profile shape for CH_4 . From the $2,903.0$ – $2,912.2\text{ cm}^{-1}$ region, a total vertical column amount of 1.510×10^{19} molecules cm^{-2} is deduced for CH_4 , corresponding to a tropospheric mixing ratio of 1.16 p.p.m.v. From the $2,915.2$ – $2,922.0\text{ cm}^{-1}$ region the corresponding values are 1.471×10^{19} molecules cm^{-2} and 1.13 p.p.m.v. The average of these two determinations of the CH_4 tropospheric mixing ratio (1.14 p.p.m.v.) is considerably lower than modern values^{5–9}. Fits with the case B CH_4 profile shape produced tropospheric CH_4 mixing ratios only 0.3% smaller than the case A values. The small magnitude of this difference results from the fact that only a small percentage of the total number of CH_4 molecules along

Fig. 1 Comparison (a) between the Jungfraujoch digitized spectrum (solid line) and a least-square best-fit to the data (plus symbols). Residuals (b) are observed – calculated values.

the atmospheric path are located in the middle and upper stratosphere where the two assumed profile shapes are different. Slightly larger changes in the tropospheric CH_4 mixing ratio were obtained by modifying the assumed profile shape in the lower stratosphere. For example, if the case A profile shape is assumed to be above 18 km and 1.60 p.p.m.v. is assumed for all altitudes below 18 km, tropospheric CH_4 mixing ratios 0.7% lower than the case A values are calculated.

As noted above, uncertainties in the assumed line parameters remain a major potential source of error in spectroscopic retrievals. Therefore, as a check on both our analysis procedure and the spectroscopic parameters that we have adopted, the CH_4 tropospheric mixing ratio has also been determined from modern data covering the same spectral region. For this purpose, we have selected a particularly dry spectrum recorded at an average solar zenith angle of 70.65° on 23 February 1981 from Kitt Peak (latitude 31.9°N , longitude 111.6°W ; elevation 2,095 m). The observations were made at 0.01 cm^{-1} resolution with the Fourier transform interferometer in the McMath solar telescope complex which is operated by the National Solar Observatory (see ref. 34 for details). To increase the validity of the comparison between the old and new data, the resolution of the Kitt Peak spectrum has been degraded by convolving the measured data with a normalized gaussian function having a width (cm^{-1}) equal to that retrieved from the Jungfraujoch spectral analysis. A correlative P – T profile based on radiosonde and global satellite measurements³⁶ has been assumed in the ray-tracing calculations. A tropopause height of 10.4 km is indicated from these results.

Assuming the case B relative mixing-ratio profile for CH_4 in the stratosphere (which is representative of measurements for the latitude of Kitt Peak), the total vertical column amount and concentration of CH_4 in the troposphere determined from the Kitt Peak spectra are 2.533×10^{19} molecules cm^{-2} and 1.56 p.p.m.v. from the $2,903.0$ – $2,912.2\text{ cm}^{-1}$ region and 2.608×10^{19} molecules cm^{-2} and 1.60 p.p.m.v. from the $2,915.2$ – $2,922.0\text{ cm}^{-1}$ region. The average of these two determinations of the CH_4 tropospheric concentration in February 1981 is 1.58 p.p.m.v., slightly lower than published *in situ* measurements for the same time and at nearly the same latitude^{6–8}. However, within our estimated experimental uncertainty of 6% (discussed below), there is agreement in the results.

The results of the fits obtained for the Jungfraujoch and Kitt Peak spectra in the $2,903.0$ – $2,912.2\text{ cm}^{-1}$ region are shown in Figs 1 and 2. The measured intensities have been normalized to the highest value in the fitted region, and the residuals

Fig. 2 Comparison (a) between the degraded Kitt Peak spectrum (solid line) and a least-squares best-fit to the data (plus symbols). Residuals (b) are observed-calculated values.

(observed minus calculated) are expressed as a percentage of the peak measured intensity. The standard deviations for the Jungfraujoch and Kitt Peak spectral fits are 1.19 and 1.44%, respectively. Although the agreement between the observed and best-fit calculated spectra is good for both data sets, some minor systematic discrepancies can be noted, especially for the higher air mass and higher signal-to-noise Kitt Peak data. The quality of the fitting results is about the same for the 2,915.2–2,922.0 cm^{-1} region.

Error analysis

A plot on an expanded scale of the observed and least-squares best-fit calculated spectra shows that a very good fit to the Jungfraujoch instrument function has been obtained with the gaussian line-shape model adopted in the analysis. However, it is important to test the sensitivity of the results to possible deviations from this model. Therefore, we repeated the Jungfraujoch retrieval for the lower wavenumber region assuming triangular and lorentzian line-shape functions. Again, a single adjustable width parameter was included in the analysis. Values for the CH_4 tropospheric mixing ratio and the standard deviation of the fit were, respectively, 1.15 p.p.m.v. and 1.26% for the triangular function and 1.24 p.p.m.v. and 1.70% for the Lorentz function, compared with 1.16 p.p.m.v. and 1.19% for the gaussian function. Plots of the results showed that the quality of the fits were nearly the same for the gaussian and triangular response functions, but that the strong wings modelled by the Lorentz function clearly did not represent satisfactorily the observational data. From these tests, we estimate that at most a 3% error in the retrieved mixing ratios can be caused by uncertainties in the line-shape function.

Scattered light and any nonlinearities in the detector-amplifier system are important sources of potential error. Both these effects are discussed in the solar atlas¹⁴, and produce negligible errors in the recording of the spectral data. The zero level was recorded at the beginning of the short section of spectrum analysed in this study. Therefore, the error in the zero level is also believed to be negligible. Although a number of solar lines can be identified in the 0.01- cm^{-1} resolution Kitt Peak spectra, their contribution to the total absorption in the analysed region is small and negligible error results from excluding them from our spectral simulation/retrieval algorithm.

In addition to the sensitivity studies already discussed, calculations similar to those presented in two previous studies^{34,36} were made to estimate the uncertainty in the CH_4 tropospheric mixing ratio caused by uncertainties in key parameters and by instrument noise. The parameters considered are the CH_4 line

Table 2 Systematic error sensitivity study

Error parameter	CH_4 tropospheric mixing-ratio error (%)	
	JF	KP

intensities S , the CH_4 air-broadened halfwidths at 296 K b_c (where b_c is the Lorentz half-linewidth at half absorption height per atmosphere), the temperature dependence of the air-broadened halfwidth n , the atmospheric temperature T and the atmospheric pressure P . The results of all the error studies are summarized in Table 2. For the Jungfraujoch data, the root of the sum of the squares (r.s.s.) of the individual uncertainty values is 7% or 0.08 p.p.m.v. The r.s.s. for the Kitt Peak spectrum is 6% or 0.09 p.p.m.v. These values have been adopted as the best estimate of the total experimental error. However, note that valid error estimates are difficult to determine for spectroscopic studies because of the difficulty in quantifying the errors for the many parameters involved in the analysis. The agreement between the Kitt Peak value and gas chromatograph determinations for the same epoch and nearly the same latitude⁶⁻⁸ suggests that we may have overestimated the total experimental error.

The calculations presented in Table 2 indicate that systematic errors in the line parameters produce about the same relative error in CH_4 concentration for both the Jungfraujoch and Kitt Peak spectra. Therefore, the average rate of increase in CH_4 has been determined more accurately than indicated by the total uncertainty limits assigned to both values. Assuming that errors in determining the rate of increase in CH_4 concentration result only from uncorrelated errors from sources c-h in Table 2, we calculate the average rate of increase of CH_4 concentration in the troposphere to be $1.1 \pm 0.2\%$ yr^{-1} from 1951 to 1981.

Comparison with previous analyses

It is important to note that the CH_4 column amount determined from our analysis is 71% of that inferred by Nielsen and Migeotte³⁷ from measurements of the $2\nu_3$ band in another set of 1951 Jungfraujoch solar spectra. In this earlier work, a curve of growth analysis method and the laboratory measurements of Goldberg *et al.*³⁸ were used to derive the total vertical column amount and the effective rotational temperature of CH_4 above the Jungfraujoch station. Although some of the discrepancy no doubt results from the use of the two different methods of analysis, we believe that most of the discrepancy is caused by the assumption of the Goldberg *et al.* intensities³⁸, which are considerably lower than several more recent studies.

Table 3 compares the Goldberg *et al.* intensities³⁸ with newer measurements³⁹⁻⁴² for the R0 and R5 lines used in Nielsen and
